CORRIGENDA

In the November 1939 number of the *Gazette*, p. 686, the article M. & B. 693 in Pneumonia, by W. J. Moody, Capt., I.M.S., should read—

M. & B. 693 IN PNEUMONIA

By W. J. MOODY, M.A., M.B., F.R.C.S. (Edin.),
CAPTAIN, I.M.S.

and on p. 692 the article 'Neuropoietin Principle in Gastric Secretion' by A. N. Shaha should read—

'NEUROPOIETIN PRINCIPLE IN GASTRIC SECRETION'

THE ÆTIOLOGY OF CENTRAL NERVOUS SYMPTOMS IN PERNICIOUS ANÆMIA

COMPOSITION—Ext. Cascara, Ext. Rhei, Jalapin, Podophyllin, Cocaine Hydrochlor., 1-20th gr. in each fluid drachm.

This preparation does not come under the Dangerous Drugs Act.

THIS excellent compound, first introduced as a general aperient and cholagogue has now become a popular remedy in that class of cases spoken of as Chronic Biliousness, in Catarrhal Jaundice and in the Jaundice of simple Hepatic Torpor. In passive or habitual Congestion of the Liver, so frequently met with, it has been used with marked benefit.

In the treatment of acute or temporary constipation, frequently met with in the convalescence from acute disease and in pregnancy, or in the constipation due to sedentary habits, to a deficiency of intestinal secretion and of peristalsis, the mixture can be prescribed with wonderful effect.

The dose is from 10 to 60 minims, according to the age and condition of the patient. One drachm is a direct aperient and is not accompanied by griping or tenesmus.

Price in England, 4 oz. bottles 10d. oz., 10 oz., 22 oz., 40 oz., and 90 oz. bottles, 12/6 lb.

This preparation is also supplied "sine Cocaina," the dose and price remaining the same.

THE ÆTIOLOGY OF TROPICAL MACROCYTIC ANÆMIA

By L. EVERARD NAPIER, M.R.C.P. (Lond.)
*Professor of Tropical Medicine, Calcutta School of
Tropical Medicine*

A NUMBER of papers that have an important bearing on the question of the ætiology of tropical macrocytic anæmia have been published during the last year. In the newer ætiological classification of anæmias (Witts, 1932), which, as far as the macrocytic anæmias are concerned, is dependent on the work of Castle, Wilkinson, Wills and others in America and Great Britain, a very comfortable place has been found for tropical macrocytic anæmia under the heading of 'errors of hæmopoiesis', as a deficiency dyscrasia due to a deficiency, relative or absolute, of Castle's extrinsic factor in the diet. The simplicity of this classification is attractive, and, further, a considerable amount of experimental clinical evidence has been adduced to show, if not the identity, at least the very close relationship of the deficient substance of tropical macrocytic anæmia and Castle's extrinsic factor (e.g., Strauss and Castle, 1932). Wills (1931), who at first seemed to be inclined to the view that the deficient substance in tropical macrocytic anæmia and the extrinsic factor were identical, later (Wills, 1934) was sceptical, and now (Wills and Evans, 1938) favours the view that the former may be an independent hæmopoietic principle. The present writer (1936) put forward the suggestion that tropical macrocytic anæmia might be due to deficiency of an independent hæmopoietic principle. When his paper was being written, Greenspon's (1936) paper had only just appeared, and the writer felt that any theory on the ætiology of a macrocytic anæmia must be considered in the light of Greenspon's work, as well as that of Castle. Further, in Greenspon's theory there was no place for tropical macrocytic anæmia, so that had this theory been accepted the ætiology of tropical macrocytic anæmia would need to have been reconsidered. Ungley (1936), criticizing the present writer's suggestion that this anæmia might be due to the absence of an independent hæmopoietic principle, wrote 'this view rests partly on the assumption of the probable correctness of Greenspon's theory', which he then proceeded by quoting recent experimental work to upset, as subsequently other workers have done more completely. Beyond the fact that Greenspon's theory made some reconsideration absolutely necessary, the writer's suggestion did not depend in any way upon the correctness of this theory. The rest of Ungley's criticism was aimed at showing that marmite did not act as an independent hæmopoietic factor in pernicious anæmia; this will be referred to below.

The writer feels that, in view of certain recent work, it is time to reconsider the classification of the anæmias as far as it applies to tropical macrocytic anæmia.

It is assumed that in tropical macrocytic anæmia as well as in pernicious anæmia the pathological changes that occur in the erythron are brought about by the deficiency of a hæmopoietic principle (hæmopoietin) which is a combination of two factors, the intrinsic factor normally present in the gastric secretions and the extrinsic factor normally present in food; in pernicious anæmia the former is absent or deficient and in tropical macrocytic anæmia the latter. Therefore, in these two diseases those pathological changes that can be attributed to the absence of this hæmopoietic principle, as well as the resulting clinical changes, should be identical. Tropical macrocytic anæmia may be a pure food deficiency and in this disease there are not necessarily any predisposing pathological lesions, but in pernicious anæmia there are very striking pathological changes in the gastric mucosa (Magnus and Ungley, 1938) which lead not only to deficiency of the intrinsic factor but to achlorhydria, deficient secretion of pepsin, and possibly other digestive disabilities. Therefore, if the current hypothesis of the ætiology of these two diseases is to be upheld, any constant differences in the pathology and clinical picture must be attributable to these gastric changes directly, and not through the deficiency in hæmopoietic principle.

Pernicious anæmia and tropical macrocytic anæmia

It will be as well to review rapidly the points of similarity and the differences between these two diseases, pernicious anæmia and tropical macrocytic anæmia. In the case of the former, the characteristic pathological changes and clinical picture are generally recognized, but as far as the latter condition is concerned it will be necessary to quote the observations of different workers and to keep in mind the possibility that we may not be dealing with a homogeneous group, particularly in regard to ætiology.

Sources of data

Wills (Wills, 1931, 1934, and Wills *et al.*, 1937) has given a fairly clear definition of the disease with which her name is rightly associated, namely the non-hæmolytic macrocytic anæmia seen in its most typical form in pregnant women but occurring also in non-pregnant women and men in the tropics, associated with a deficient dietary, and curable by marmite or crude liver extract.

Fairley *et al.* (1938) give the data from 37 cases of macrocytic anæmia (out of a total of 39 cases of anæmia) amongst Macedonian refugees, men and women; there were amongst these hæmolytic and non-hæmolytic cases, and the clinical picture was complicated by a cent-per-cent malaria infection, either past or present.

The present writer's experience includes about 50 cases of anæmia a year for the last four years treated in the Carmichael Hospital for Tropical

Diseases, Calcutta, in which fairly complete investigations have been carried out (including sternum puncture during the last two years); about half of these were of the macrocytic type, hæmolytic or non-hæmolytic; from amongst these, selected cases have been reported from time to time (Napier, 1936, 1938; Napier *et al.*, 1938). The majority of these patients were males. Two separate groups, 52 and 57 cases respectively, of anæmic pregnant women were investigated in two different localities in Assam (Napier and Bilimoria, 1937, and Napier and Mazumdar, 1938); in both groups the picture was complicated by malaria and hookworm infection; in the latter locality malaria was a more serious problem than in the former, and the reverse was probably true of hookworm infection. In each group the anæmia was 'mixed' but in about half the cases there was evidence of a 'macrocytic tendency' and in those of the latter group of 'marmite-liver factor' deficiency. Nearly all were of the hæmolytic type.

Similarities.—The points of similarity are, that they are both macrocytic anæmias with the signs and symptoms common to all anæmias, that the raw-beef tongue of pernicious anæmia does occasionally occur and more frequently there is only some tenderness in tropical macrocytic anæmia, that loss of appetite, dyspepsia and low irregular fever are common in both (but are symptoms that may occur in any anæmia), and finally that response to oral or parenteral treatment with crude liver extract is a common factor.

Differences.—As far as the symptomatology is concerned the outstanding point of difference is the absence of neurological symptoms in tropical macrocytic anæmia; all the workers referred to above have laid stress on this point. Slight numbness and tingling of the toes and feet and diminished knee jerks are the only neurological symptoms that the present writer has ever seen in these cases, and these only very rarely. In a large number of these cases the red cell count has been below a million per c.mm. and in some as low as half a million, so that it is certainly not a matter of degree of the anæmia. Sore tongue and glossitis are not nearly so common nor so characteristic in tropical macrocytic anæmia.

In the blood picture the differences are numerous.

Red cells.—The mean cell volume in both conditions is high, but both Fairley's (1938) observations (though he has made certain reservations on account of the method adopted in staining) and those of the present writer* suggest that the mean cell diameter is only slightly above normal, that is to say there is a spherocytosis, in tropical macrocytic anæmia. On the other hand the present writer found in typical uncomplicated tropical macrocytic anæmia (Napier, 1936) that, even when the Price-Jones curve was shifted to the right, the curve did not usually show the degree of flattening that occurs in pernicious anæmia. If the figures quoted by Price-Jones (1933) may be taken as typical of pernicious anæmia, the coefficients of variation given by Fairley for his

cases of tropical macrocytic anæmia were with one exception well below that of the typical pernicious curve. Poikilocytosis is also less marked in tropical macrocytic anæmia. In pernicious anæmia there is usually a slight initial reticulocyte increase, 3 or 4 per cent, but in Wills' experience this is never the case in uncomplicated tropical macrocytic anæmia; this is in keeping with the present writer's experience, only however as far as the non-hæmolytic cases are concerned, but this point will be referred to later. Whilst references are made frequently to the presence of 'megaloblasts' in the peripheral blood, the present writer has never seen the typical hæmoglobinized megaloblast of pernicious anæmia in the peripheral blood in a case of tropical macrocytic anæmia, though occasionally he has seen the basophilic megaloblasts that occur in normal bone marrow.

White cells.—Some degree of leucopenia is the rule in pernicious anæmia. In the non-pregnant hæmolytic cases of tropical macrocytic anæmia the present writer has usually found a marked degree of leucopenia, but this was not usually so in the pregnant women nor in the non-hæmolytic cases. Wills also noted that a leucopenia was not constant but explained this by the normal leucocytosis of pregnancy and by the fact that many of her post-partum cases suffered from slight degrees of sepsis. Neither has the characteristic inversion of the polymorphonuclear/lymphocyte ratio nor the right-handed shift in the Arneht count, characteristic of pernicious anæmia, been noted frequently in tropical macrocytic anæmia.

The van den Bergh reaction.—In pernicious anæmia the indirect van den Bergh is usually positive, 1.0 to 2.5 mgm. per 100 c.cm. (Vaughan, 1934). According to Wills, in uncomplicated tropical macrocytic anæmia it is never positive. The present writer has seen many typical cases of tropical macrocytic anæmia with negative van den Bergh reactions, but the large majority of both his and Fairley's published cases show a positive van den Bergh indirect reaction, *i.e.*, bilirubin above 1.0 mgm. per 100 c.cm. This point will also be referred to later.

Gastric analyses.—As the anti-pernicious-anæmia factor, it is believed, is secreted by the oxyntic cells, there is naturally a parallelism between the secretion of acid and the anti-pernicious-anæmia factor. Complete histamin-fast achlorhydria is, for practical purposes, always found in pernicious anæmia; the incidence in tropical macrocytic anæmia is the same as in the general population, but in the writer's experience the acid secretion in the stomach is slightly below normal and slightly lower than in other anæmias. Wills found the same in her pregnant cases and explained it on the grounds of a normal lowered acid secretion in pregnancy.

Sternum puncture.—Here a certain amount of misunderstanding has arisen through confusion in nomenclature. The red-cell elements are usually distinctly increased, but not so much as

* In fact in case 5, below, the mean cell diameter is so low that one almost suspects an error of technique, but this explanation cannot be accepted.

in microcytic iron-deficiency anæmia; there is also a marked increase in the (normal) basophilic megaloblasts at the expense of more mature normoblasts, but the present writer has only very rarely seen a (pathological) hæmoglobinized megaloblast, the characteristic cell of pernicious anæmia, in a sternum-puncture smear from a case of tropical macrocytic anæmia. Fairley and his co-workers (1938) have made the same observation, and say 'Ripening sufficient to produce a really pink cytoplasm in a cell with finely stippled nucleus was a rarity'.

Treatment.—A large amount of work on pernicious anæmia has been done, but the relevant points are summarized in the following four paragraphs:—

(a) Yeast extract or marmite alone in sufficient doses will produce a hæmopoietic response and eventually a cure in tropical macrocytic anæmia (Wills, 1931; Napier, 1936). Massive doses of yeast extract produced hæmopoietic response in 10 out of 18 cases of pernicious anæmia; an extract made from yeast given by mouth similarly produced a response, but the same extract parenterally did not (Ungley and James, 1934).

(b) Anahæmin produces a response in pernicious anæmia in such small doses as to suggest that almost the whole of the active substance is present in this fraction. Anahæmin, in doses that would produce a maximum response in pernicious anæmia, sometimes produces no hæmopoietic response in true cases of tropical macrocytic anæmia (Napier, 1938, Wills and Evans, 1938, and case 1 below), but in certain cases even moderate doses produce a response (Napier *et al.*, 1938) and, apparently more frequently, massive doses produce a response, which may be delayed and slightly submaximal (Wills and Evans, 1938, and cases 2 and 3 below).

(c) The insoluble (saturated ammonium sulphate) fraction of campolon (comparable to anahæmin) is inactive in tropical macrocytic anæmia and produces a maximum response in pernicious anæmia. The soluble fraction of campolon produces a maximum response in tropical macrocytic anæmia (Wills and Evans, 1938), and also surprisingly in pernicious anæmia (Wills *et al.*, 1937).

(d) Campolon and other 'crude' liver extracts produce a maximum response in both conditions.

Discussion.—As it is in the response to treatment that the most significant similarities and also differences are found, it will be as well to consider this first. The points will be discussed paragraph by paragraph.

(a) These observations are in keeping with the hypothesis that identifies the deficient substance in tropical macrocytic anæmia and Castle's extrinsic factor, but do not exclude the possibility that yeast extract contains both these factors. The response in the cases of pernicious anæmia is explained on the grounds that in the gastric secretions of these cases there remained some intrinsic factor which, when the yeast

extract was given parenterally, could not be utilized. This argument cannot be used to disprove the independent-hæmopoietic-factor hypothesis in tropical macrocytic anæmia unless one assumes, as Ungley seems to have done, that in pernicious anæmia and tropical macrocytic anæmia the pathological processes are identical. Further, his single experiment showing the failure of parenteral yeast extract will have to be repeated. Against this the present writer can quote a case (4) apparently showing a contrary effect, but again this is a single case and not entirely convincing. (For more than two years the writer has been trying to obtain suitable yeast extracts for parenteral injection, but promised samples have never arrived.)

(b) These observations suggest that whilst the whole of the hæmopoietic principle of liver extract, *i.e.*, the combined intrinsic and extrinsic factors, is present in the anahæmin fraction, the deficient factor of tropical macrocytic anæmia is not present or only present in small amounts; this precludes the complete identity of the extrinsic factor and the substance deficient in tropical macrocytic anæmia, but suggests that each may be a combination of substances and that there is some overlapping.

(c) The experiments with the soluble and insoluble fractions confirm the above conclusions, particularly with reference to there being some overlapping, unless one takes the view that by this method the separation of the two fractions is imperfect.

(d) This simply shows that both factors are abundantly present in crude liver extracts.

If one takes into consideration the work of Sudbarow and Jacobson (1936) who claim to have shown that there are at least three fractions in the hæmopoietic principle, the same possibility must be allowed to the hæmopoietic principle of tropical macrocytic anæmia, and one soon finds oneself in a morass of hypotheses from which the only hope of extrication is by very careful quantitative experimental work.

However, to summarize, this recent work on treatment does seem to indicate quite clearly that the deficient substance in tropical macrocytic anæmia is not identical with the extrinsic factor, and that, though in many substances they are closely associated, they can be separated, almost if not quite completely.

As far as the pathology of the two deficiencies is concerned, there is, in the writer's opinion, considerable evidence that the bone-marrow reaction in tropical macrocytic anæmia is different from that in pernicious anæmia; in the latter there is a dysplasia at the megaloblastic level with the formation of pathological megaloblasts, whereas in the former there is a general hyperplasia in the red-cell-forming elements with excessive multiplication but delayed maturation at the megaloblast level, or an anaplasia rather than a dysplasia. In tropical macrocytic anæmia the effect of the deficiency is shown a

little later in the life of the maturing red cell than in pernicious anæmia.

Another important difference between the two diseases appears to be the van den Bergh reaction. For the hyperbilirubinæmia of pernicious anæmia, the explanation that is now given (Witts, 1932) does not seem to be entirely convincing; it is said to be due to the failure to re-utilize the products of normal hæmolysis. This seems to supply the explanation for the excessive storage of iron (hæmosiderin) that occurs in pernicious anæmia, as there is no natural outlet for this substance, but not of the non-iron-containing pigments. Though the non-iron-containing pigments are probably re-utilized to some extent in the formation of hæmoglobin, there is a natural outlet for these pigments and it is only when they are present in excess (in the event of a sudden hæmolysis), or when the outlet becomes blocked or otherwise inefficient (hepatic damage) that hyperbilirubinæmia results. But it seems improbable that the small amount of pigment that is thrown back into circulation by the failure of hæmopoiesis could cause an excess that could not be dealt with by the normal processes of elimination. In the iron-deficiency anæmias, the immediate response to iron administration shows that there is no lack of blood pigments; if iron is not given these are not utilized but their non-utilization does not lead to hyperbilirubinæmia.

Is not the other explanation more probable, namely, that the defective products of hæmopoiesis are readily destroyed by a relatively normal reticulo-endothelial system?

If we accept this second explanation it is easy to understand why there is a lower level of blood bilirubin in tropical macrocytic anæmia where, though the cells are larger than normal, there is less anisocytosis and poikilocytosis and therefore fewer defective cells to attract the attention of the normal reticulo-endothelial tissues, and less hæmolysis. Whether or not this explanation can be accepted, the difference in the bilirubin level in the two diseases seems to be an important difference and to suggest a fundamental difference in the pathological processes of these two anæmias, when they are uncomplicated. The incidence of hyperbilirubinæmia in most of the present writer's and in Fairley's cases can be attributed to a different cause; this is a point that will be discussed later.

Conclusion.—It is quite evident that there are fundamental differences in the pathology and in the resultant clinical picture in these two conditions, and, to return to the original proposition, it seems very improbable that these differences can be attributed directly to abnormalities in the gastric mucosa (other than failure to secrete intrinsic factor) in pernicious anæmia. Therefore, the present hypothesis of the ætiology of these two diseases, which identifies the extrinsic factor of pernicious anæmia and the food-deficiency factor of tropical macrocytic anæmia, cannot be accepted, and the suggestion that the

food deficiency in tropical macrocytic anæmia is the deficiency of an independent substance, or group of substances, necessary for the development of the red cells at the megal-erythroblastic level, just as iron is at the normoblastic level, must be seriously considered.

In the meanwhile the present writer proposes to adopt this as a working hypothesis for discussing the hæmolytic group below:—

ILLUSTRATIVE CASES

Case 1.—A male, Mohammedan, aged 23 years, a student. He took fish but no meat and seldom any milk. He lived in a malarious district in Bengal and had suffered from malaria from time to time. Recently, he had had fever almost continuously and had been treated for kala-azar. He was also becoming anæmic and gave a history of splenic enlargement.

On 18th September, 1938, he was admitted in a weak, anæmic and emaciated condition. His spleen was only just palpable. His van den Bergh (indirect) test was positive at first but later, before he had had any effective treatment, became negative. His anæmia was macrocytic and sternum puncture showed hyperplasia of the red-cell elements and a fair number of 'megaloblasts' (see tables I and II).

He was given 5 injections of anahæmin (2 c.c.) on consecutive days from 21st September. There was little evidence of response and on 1st October he was given an injection of Hepabos (4 c.c.) which was repeated the next day.

On 10th October his red cell count had fallen to half a million. He was then given an injection of Campolon (4 c.c.) which was repeated on the next two days. After this his condition became very critical and for two days he was semi-conscious and did not respond to questions. On 15th October (Saturday) a blood transfusion was ordered, but was not given as no donor of the same group was available. The writer did not see him again until the Monday morning when the clinical picture was entirely changed and he was sitting up in bed. A blood count showed a reticulocyte count of 28 per cent (this was possibly not the peak as no counts had been done on the previous two days), an increase in red cells and a marked drop in the size of the cells. The reticulocyte count fell by stages on the next three days to 6 per cent and the red cell count continued to rise. He is still under treatment (see chart).

Case 2.—Hindu male, aged 27 years, a student. He had lived in Calcutta for a number of years, but had had attacks of malaria from time to time. He was a strict vegetarian and took no fish, eggs, or milk.

He was admitted on 24th September, 1938, complaining of low irregular fever, a pain in the abdomen, increasing weakness and breathlessness of some duration. There was evidence of anæmia, but no sore tongue or splenic enlargement. Gastric analysis showed a low acid curve. The result of sternum puncture is shown in table II; the initial blood count showed a typical macrocytic anæmia (see table I).

Six daily doses of 200 mgm. anahæmin, total 1,200 grammes, were given from 27th September to 2nd October. From 1.5 per cent, the reticulocytes rose to 8 per cent on 3rd October, 14 per cent on the 4th and 22 per cent on the 5th October. The apex of the reticulocyte curve was on the 9th day from the beginning of anahæmin; the red cell count rose sharply and the size of the cell diminished, but neither improvement was maintained, so on 21st October Perhepar (Richter) was given, 2 c.c. daily. The day this was given the patient had a rigor and benign tertian parasites were found in the peripheral blood. His temperature rose daily to 102°F. for three days, but came to normal again without any specific treatment and has remained normal since; the Perhepar was continued up to three daily doses of 2 c.c. each. The next count, which was the last one made, showed a further rise in the red

cells and a drop in the mean corpuscular volume. He is still under treatment (see charts).

Case 3.—A Mohammedan male, aged 27 years, a land-owning cultivator. He was a strict vegetarian but recently on medical advice he had taken a little fish. He gave a history of diarrhoea for nearly two years with occasional fever and increasing weakness.

He was admitted on 13th September in a precarious condition, weak, emaciated, and anæmic; he had a bed sore and he had continuous loose motions which he sometimes passed in his linen. He had a red, sore, denuded tongue and a sore mouth. His spleen was not enlarged. His blood picture was one of macrocytic anæmia. His van den Bergh reaction was negative and remained so throughout. Sternum puncture showed a general hyperplasia of the red-cell elements but the reaction was normoblastic (table II). Fractional gastric analysis without histamin showed a little free acid in one sample only.

His dehydrated condition demanded glucose and saline intravenously. After six daily injections of anahæmin, a total of 1,200 grammes, the reticulocyte percentage was 4, the red cell count had fallen (this was probably on account of the previous dehydration), and the mean cell volume had increased. As his condition was still serious, fearing the possible failure of anahæmin, we gave 'Perhepar' (Richter) 4 injections of 2 c.c. each. On the second day of these injections, that is, the 8th day from the commencement of the anahæmin, the reticulocytes rose to 19 per cent, and on the following day to 33 per cent. The patient's condition improved, the red cells increased and the size of the cells came down and continued to do so, reaching 3,400,000 per c.mm. and 101 cu.µ., respectively, on 19th October without any further specific treatment. He is still under treatment (see chart).

Case 4.—A Hindu female, aged 28 years, married, three children, not now pregnant. Admitted into hospital on 27th May, 1936, with moderate anæmia of the macrocytic type. Gastric analysis showed a normal acid curve.

She was given daily intramuscular injections of 'yeast extract' for ten days without any apparent effect; later, she was given another fraction of yeast which appeared to lead to an improved blood picture. Later, whole marmite was given by mouth and the improvement was maintained until a practically normal picture was reached (see chart and table I).

Discussion on illustrative cases

Case 1 is not a truly hæmolytic case although the occasional positive van den Bergh indirect reaction is not explained. Massive doses of anahæmin and adequate doses of Hepabos were apparently entirely inactive, but later Campolon produced a classical response; a 28 per cent reticulocytosis on the 7th day was recorded, but

vicious circle of deficient invalid diet—specific malnutrition—nutritional anæmia and mucosal dysfunction—further diarrhoea—mal-absorption—further malnutrition—and so on. This circle was broken immediately by a suitable diet and injections of liver preparations, and two years' diarrhoea changed to constipation within a few days. As far as the blood condition was

concerned the absence of any response after six days of anahæmin led to a possibly premature conclusion that it was inactive and the injection of a 'crude' liver preparation, so that the interpretation is doubtful, though it seems possible that the late, but maximal and sustained, response in this case may have been brought about by a combination of anahæmin and the 'crude' liver preparation.

it is possible that the peak was reached before this.

Case 2 was again not a typical hæmolytic case; the hyperbilirubinæmia at the first examination was probably caused by a recent malarial attack, and on the second occasion a malarial attack was demonstrated. After anahæmin the reticulocyte curve did not start to

Case 4 is not a satisfactory one. There is however some suggestion that a yeast extract given parenterally had a curative effect. Though the lowness of the reticulocyte response might be explained on the high initial red cell count and the low potency of the extracts, the whole improvement might be attributed to rest in bed and a good diet.

Before treatment.

rise until the 7th day and did not reach its peak until the 9th day; further, the rise was sub-maximal. This suggests that the early doses had little effect and that the result was only achieved by the mass action of the repeated doses. The failure to sustain the improvement in the red cell count, and the immediate improvement despite a malarial attack when injections of 'crude' liver extract were given, also point to the fact that the effect of even this massive dose of anahæmin was not maximal.

Case 3 was quite definitely non-hæmolytic. The history was strongly suggestive of food deficiency complicated by diarrhoea, which started a

THE HÆMOLYTIC GROUP

In the paper already referred to, the present writer (Napier, 1936) expressed the view that the cases of macrocytic anæmia which he was then reporting, though exhibiting some common features, notably response to marmite, could not be grouped as Wills' tropical macrocytic anæmia and were not themselves a homogeneous group. Further experience has however tended to make him modify this opinion. By their response to treatment by different liver 'fractions' and different liver preparations, he hoped to separate these anæmias into distinct ætiological groups, but up to the present the results have been singularly disappointing (Napier, 1938, and Napier *et al.*, 1938); one finds in clinically and hæmatologically identical cases classical response to anahæmin in one, late response in another, and no response in a third, and on the other hand a non-hæmolytic case with no splenic enlargement responding in exactly the same way

as a hæmolytic case with high initial reticuloocyte count and a large spleen. The view to which the writer is now inclined is that the deficient factors in these two types of macrocytic anæmia are groups of substances, if not identical, closely allied and showing a considerable amount of overlapping, but that the causes of the deficiency or relative deficiency are various, as in the case of iron-deficiency anæmia, and that one of the most important ones, especially in tropical and sub-tropical countries, is the hæmolysis associated with post-malarial reticulo-endotheliosis,* usually shown clinically by splenic enlargement.

This view that excessive hæmolysis might determine the deficiency in an individual on a border-line diet has already been put forward by the writer (Napier, 1936) and is strongly supported by recent experience; Napier and Mazumdar (1938) in discussing the part played by malaria in the production of macrocytic anæmia in their cases say, 'our suggestion is that it is not the acute attack—which is often not accompanied by a positive van den Bergh reaction—but the chronic state with the damaged reticulo-endothelial tissue in the spleen and elsewhere that is most likely to be the determining factor in producing this anæmia' and in their conclusions they suggest that the anæmia is produced by 'a relative deficiency in important food factors probably associated with the vitamin-B₂ complex' and 'by a state of chronic malaria'. Fairley and his co-workers (1938) have also suggested that, when dietary deficiency complicates excessive blood-cell destruction by a hypertrophied reticulo-endothelial system, this may lead to a 'panmyelopathy and megaloblastic hyperplasia in the bone marrow'; they visualize a condition in which 'the reticulo-endothelial system, irritated, activated and hypertrophied as a result of repeated malarial infections, phagocytoses those non-parasitized

abnormal corpuscles in considerable numbers with the production of hæmolytic anæmia', and consider that tropical macrocytic anæmia should be divided into a hæmolytic and a non-hæmolytic group.

To be more explicit the writer postulates a substance (or substances) normally present in marmite and crude liver extract which is required *quantitatively* for the normal maturation of red cells at the megal-erythroblast level; it is a substance that is possibly stored in the body, but is not a by-product of hæmolysis, or, if it is, is not re-utilizable, as is iron, for example. A normal mixed diet contains sufficient of this substance for normal requirements, and, together with the possible storage reserve, for emergencies such as hæmorrhages and moderate hæmolyses, but in severe and chronic hæmolyses—which demand a much greater corpuscular replacement than any non-fatal hæmorrhage—the reserve is rapidly exhausted and there may be a deficiency, which will be exaggerated if there is a deficiency of this substance in the food. A diet grossly deficient in this substance will also in time give rise to pathological changes, which will be exaggerated by conditions of extra demand such as pregnancy, or of mal-absorption, as in sprue and lenteric diarrhœa (case 3).

Case 5 (1936).

* The writer is using this term in full knowledge and in defiance of the fact that it has already been applied to monocytic leukaemia, an application that Forkner (1938) and others unreservedly condemn.

The present application of the term seems to be justified in that the body reaction to malarial infection is both hypertrophy of the fixed reticulo-endothelial tissues and mobilization in the blood of the free reticulo-endothelial cells, the histiocytes (Napier, Krishnan and Lal, 1932).

The following illustrative case is a very good example of a typical case of the hæmolytic type of tropical macrocytic anæmia as encountered in Bengal:—

Case 5.—The patient was a male, aged 19 years, an orphan of poor cultivator class. He was not a strict vegetarian, but the opportunity for eating anything but rice seldom arose; living in the vicinity of Calcutta, his family had acquired the habit of eating polished rice.

He gave a history of fever on and off for many years, increasing enlargement of the spleen for a few years, and weakness and other symptoms associated with anæmia. Kala-azar was suspected, but was soon excluded.

He was admitted into hospital on 8th August, 1936. He had a low irregular fever for a week or so. His liver was enlarged. His spleen was firm, but not hard, and reached almost to the navel. A puncture showed no leishmania, no malarial parasites, nor malarial pigment; the smear showed many macrophages, and many nucleated red cells, also some groups of dividing erythroblasts which suggested that the spleen contained foci of extra-medullary hæmopoiesis. The gastric analysis showed a low free-acid curve. Sternum puncture was not done. No malarial parasites were ever found in the blood. His initial blood count is shown in table I (above).

He was given the ordinary hospital 'full' diet, which is a good mixed diet of about 2,700 calories, but no special foods nor medicines other than purgatives. His blood picture steadily improved and the spleen decreased in size. Cinchona febrifuge was given on 20th August for seven days, as a routine procedure; no parasites had been found nor was there any fever at the time. The red blood cell curve appeared to rise more rapidly after this, but the reticulocyte percentage fell. Later, marmite and iron were given

Case 5 (1938).

at different times, but these did not seem to affect the progress in any way. At the end of two and a half months the red cell count had reached four millions: the rest of the blood findings are shown in table I. The spleen was just palpable but the liver was normal. The patient considered himself cured and left hospital (see chart, page 7).

The evidence of the chart suggests that he would have improved and his blood would have returned to normal without any treatment other than rest in bed and a good diet.

This patient provides a very good example of chronic malarial reticulo-endotheliosis, in which repeated malarial infection had led to hyperplasia of the reticulo-endothelial tissues, in the liver and spleen in particular, which not only destroyed malarial parasites and prevented their multiplying to the extent of producing a clinical attack of malaria, but also phagocytosed uninfected but damaged and abnormal red cells. Thus, a vicious circle was set up in which irritated and over-activated reticulo-endothelial tissue phagocytosed red cells almost indiscriminately and thereby aggravated the anaemia and increased the demand for haemopoietic substances, the supply of which was already inadequate; this led to further disordered haemopoiesis and the production of more defective red cells, further hyperplasia of phagocytic cells, and further hypertrophy of reticulo-endothelial tissues. This vicious circle was broken by an increased supply of the haemopoietic principle in the food which ensured more orderly haemopoiesis, reduction in the number of abnormal cells, and therefore in the work of the phagocytic tissues, so that a general retrogression of this tissue set in. Though it may have allowed for the return of the blood picture to normal and the disappearance of evidence of excessive haemolysis—the reticulocytosis and the hyperbilirubinaemia, this retrogression only reached a certain point and still left an hypertrophied reticulo-endothelial system which could easily be reactivated

by repeated malarial infections combined with dietary deficiency.

In this particular case the patient returned to his same poor home and poor diet, and though there was no positive evidence of another malarial infection he reported sick again on 1st August, 1938, almost exactly two years after his first admission with a similar history of some months' irregular fever, and in the same condition, except that his general condition was worse and the anaemia more marked.

The blood picture at the time of this admission is given in table I and chart on page 7. A spleen puncture showed a state of affairs exactly the same as on the previous occasion, evidence of both haemolysis and extra-medullary haemopoiesis, and the sternum puncture showed a general erythroblastic hyperplasia, but few megaloblasts (see table II). Despite his previous history, we felt that his serious condition demanded active measures and after a few days he was given a single injection of anahamin, 200 mgm.; this was not followed by any improvement in the blood picture and on 19th

August he was given 5 c.cm. of 'Hepabos'; this dose was repeated on 20th and 21st August. The reticulocyte count had been irregular but on 24th August there was a sharp rise from 7 to 17 per cent followed by a fall to 6 per cent in two stages. During his stay in hospital he was given other liver preparations and on each occasion there was some evidence of acceleration of improvement; his blood improved to well over 4 millions in the same period of two and a half months, despite the original lower level and the slow improvement at the beginning (see table I and chart). Again, the spleen was reduced considerably, being now level with the costal arch. The van den Bergh reaction was positive at first (2 mgm. per 100 c.cm.), but decreased throughout treatment and was finally negative.

The sequence of events in this second attack is interpreted as follows: The patient returned to his unsatisfactory diet and his malarious home; he was submitted to further malaria infections; this reactivated the phagocytic cells in the already increased bed of his reticulo-endothelial tissues and led successively to increased blood-cell destruction, increased blood formation, exhaustion of the inadequate supply of haemopoietic principle, haemopoietic dysfunction with the formation of abnormal cells, and a repetition of the whole vicious circle. On this second occasion, as the condition had progressed further, more of the haemopoietic principle than could be supplied in the diet was required, but the massive doses supplied in the liver preparations were sufficient to break the circle and bring about an almost complete cure, except possibly for some further damage to the reticulo-endothelial tissues.

It will be seen that the cause of the hyperbilirubinaemia in the haemolytic type of tropical macrocytic anaemia is different from that in pernicious anaemia: in the latter it is due to increased phagocytosis of gravely abnormal red cells by normal reticulo-endothelial tissues, whereas in the former it is due to increased phagocytosis of normal and slightly abnormal

cells by hypertrophied and abnormal reticulo-endothelial tissues.

Future investigation.—The writer is painfully aware that he has done little towards clarifying the aetiology of tropical macrocytic anaemia and nothing towards identifying the deficient substance. Dr. Lucy Wills has done invaluable work with her experiments on the nutritional anaemia of monkeys and it is possibly along these lines that further clarification may be sought, but there are always limits to the analogy between pathological processes in two different genera. As far as clinical experimental work is concerned, careful *quantitative* work with only purified fractions of autolysed yeast and liver extract seems to offer the best prospects.

Summary

The identity of the food substance deficient in tropical macrocytic anaemia and Castle's extrinsic factor (of pernicious anaemia) is questioned.

The differences between these two diseases, particularly with reference to the response to treatment, are discussed and illustrative cases cited.

The writer considers that recent work, which is discussed, has added support to his suggestion that in tropical macrocytic anaemia the deficient substance is not identical with Castle's extrinsic factor but is an independent haemopoietic principle.

The writer, modifying his previous opinion, considers that there is a close relationship between the haemolytic and non-haemolytic types of tropical macrocytic anaemia and that malaria is an important predisposing factor in the former.

A typical case of this type of haemolytic anaemia is reported and the writer's interpretation of the mechanism of the production of the anaemia in this case is given.

Lines for future work are suggested.

Acknowledgments

My thanks are due to my assistants, Drs. C. R. Das Gupta and D. N. Mazumdar, for the blood counts in the 4 recent cases quoted (the latter is a worker under the Indian Research Fund Association); also to the British Drug Houses and other manufacturers for a free supply of the preparations used.

 College, Calcutta, and Bacteriologist to the Government
 of Bengal*

(From the Department of Pathology and Bacteriology,
 Medical College, Calcutta)

THE spleen is an organ which has long been known to be associated with important functions of life. By its spontaneous rhythmic contraction the organ acts as an ancillary respiratory organ (Roy, 1881, Schäfer and Moore, 1896, Barcroft, 1926, and Barcroft and Stephens, 1927) and it can supply additional oxygen carriers when such a demand arises (McNee, 1931). The spleen, again, is one of the sites where destruction of old and damaged red blood cells takes place, which process results in the production of bile pigments (McNee, 1923). Though not yet fully understood, there is still ample reason to believe that the spleen is related with the destruction of thrombocytes (Rosenthal, 1925). Again there are equally good reasons to believe that this organ has an intimate relationship with digestive metabolism and specially of cholesterol metabolism (MacAdam and Shiskin, 1923, Abelous and Soula, 1920, 1925). For a long

* Dr. Bilimoria spells his name with one 'l'. Confusion has arisen through certain editors altering the spelling to 'Billimoria' without reference to the author. Others have allowed him to use the spelling he prefers. As uniformity seems desirable, we propose to adopt the correct spelling, ignoring the previous errors.

abundance (plate II, figure 4). This type of splenomegaly which is the result of a chronic and repeated malarial infection although it diminishes in size to some extent often persists for a very long time after the infection is cured, sometimes throughout the greater part of life in spite of all the treatment given to the patient.

The types of splenomegaly described above are always accompanied by varying degrees of hepatic enlargement which is found to be due to the accumulation of pigments in the Kupffer's cells as well as marked engorgement of the liver capillaries (plate III, figure 5). These fixed reticulo-endothelial cells not only proliferate in number but also increase in their size exactly in the same manner as they do in the spleen. As it takes a very long time to dispose of their heavy load of inert pigment the hepatic enlargement also persists for a long period like the splenic enlargement. The hepatic cells may contain hæmosiderin granules and also show some degree of fatty change but no hæmozoin pigments are ever found inside their cytoplasm. It may be definitely stated that in malaria, inflammatory reaction of any kind is not met with in this organ, although in very chronic and long-standing infections one may find collections of mononuclear cells limited only to the portal spaces. If we take cellular accumulations as evidence of irritation they might produce some fibroblastic reactions in these areas, giving rise to thickening of the connective tissues, but even such a change is not constant in the average chronic case of malaria met with in the autopsy room. Such a change, however, can neither produce an appearance of portal cirrhosis nor the clinical phenomena of the common cirrhosis of the liver. The hypothesis of cirrhosis of the liver of malarial origin, although advocated in older times, cannot be supported in view of the histological findings enumerated above.

Kala-azar.—Now let us see what changes we may find in the spleen when the individual is infected with *Leishmania donovani*. To all intents and purposes, the series of changes are essentially the same, modified only by certain biological characteristics of the infecting parasites. When these latter gain entrance into the body of the host, they are at once phagocytosed by the reticulo-endothelial cells which instead of killing them appear to give them a shelter for growth and multiplication. The parasites do not seem to remain extra-cellular for any length of time, but are taken up immediately inside the cytoplasm of the clasmatoocytes, some of which may be found to contain hundreds of them. Wenyon (1926) after Nattan-Larrier reported the presence of the parasites inside the hepatic cells; our experience, however, is different in this respect. In fact leishmaniasis is essentially an infection of the reticulo-endothelial system (De, 1927 and 1934). The nature of the pathological changes which are brought about in the spleen is therefore exactly similar to that found in

malaria, except that there are no pigments; their place is however occupied by the parasites themselves. As the infective process is a chronic one in comparison to that in malaria we never encounter—in the post-mortem room—such acute changes in the spleen, especially the enormous engorgement of the organ with blood and the extreme degree of stretching of the capsule. In a case with fairly heavy infection the duration of illness lasting for more than 3 months, the spleen is greatly enlarged, being much larger than in any case of malaria of similar duration. It is soft in consistence and has a dull red or chocolate colour. The surface is smooth and the capsule is somewhat thinned. The organ cuts easily and the sensation is that of cutting through a muscle or liver. The cut surface which bulges out presents small alternate elevations and depressions (plate I, figure B), the former representing the congested and hyperplastic pulp areas and the latter the region of the atrophic Malpighian follicles with the arteriole. Histological examination reveals a very characteristic picture. The pulp consists of nothing but large phagocytic mononuclear cells—the reticulo-endothelial cells, containing the parasites in large numbers and many dilated blood sinuses. Both the stroma and the reticulum are very insignificant (Shanks and De, 1931). The pulp areas become larger and encroach considerably on the follicles which *pari passu* diminish in size and, in a fairly long-standing case, disappear almost completely, leaving behind just a few lymphoid cells aggregated around an arteriole. The parasites are quite easily made out always inside the large mononuclear cells, their number varying somewhat according to whether the case is an acute or a chronic one. As a rule, these are always very numerous in an acute case but their number is not at all insignificant in a chronic one. The vascular spaces which are widely dilated and engorged with blood (plate III, figure 6) show also many large mononuclear cells containing the parasites (plate III, figure 7). The trabeculae which form such prominent structures in a chronic malarial spleen are very few and far between and many of them are thin and atrophic looking. No hæmozoin pigment can be detected

EXPLANATION OF PLATE I

Fig. A.—Coloured diagram of a section of spleen from a case of chronic malaria (malignant tertian infection) showing the characteristic slate blue colour with increase of connective tissue trabeculae standing out as whitish strands. (These are not very clear in this plate.)

Fig. B.—Coloured diagram of a section of spleen from a case of fairly acute infection with *Leishmania donovani*. It shows a general view of the substance of the organ after it is cut open. The congested and hyperplastic pulp areas may be seen as prominent elevations whereas the depressions represent the areas of the atrophic Malpighian follicles.

Fig. C.—Coloured diagram of a section of spleen from a case of 'Bengal splenomegaly' showing the general appearance of the substance. Compare this picture with that in the section of kala-azar spleen in plate III, figure 8.

PLATE I

Fig. B

PLATE II

Fig. 1.—Photomicrograph (high power view) of a section of spleen from a case of acute malaria (malignant tertian infection) showing hemozoin pigment inside the cytoplasm of the endothelial and large mononuclear cells.

Objective—Leitz no. 8 mm. (apochromat).
Ocular—Leitz no. 8 × (periplan.).

Fig. 2.—Photomicrograph (low power view) of a section of spleen from a case of chronic malignant tertian infection showing marked diffuse pigmentation and connective tissue hyperplasia throughout the substance of the organ.

Objective—Zeiss no. 10 (apochromat).
Ocular—Zeiss no. 4 (compens.).

Fig. 3.—Photomicrograph (high power view) of a section of spleen from a case of subacute malaria, showing the cytoplasm of the phagocytic mononuclear cells filled with hemozoin pigment.

Objective—Leitz no. 6a.
Ocular—Leitz no. 8 × (periplan.).

Fig. 4.—Photomicrograph (low power view) of a section of spleen from a case of chronic malaria showing increase of reticulum fibres in the organ.

Objective—Leitz no. 6a.
Ocular—Zeiss no. 4 (compens.).

Fig. 5.—Photomicrograph (high power view) of a section of liver from a case of acute malarial infection showing enlargement of the Kupffer's cells and marked accumulation of malarial pigment within their cytoplasm. It will be seen that the hepatic cells are absolutely free from pigment.

Objective—Leitz no. 6a.

Ocular—Leitz no. 8 × (periplan.).

Fig. 6.—Photomicrograph (low power view) of a section of spleen from a case of acute kala-azar showing the widely dilated and engorged blood sinuses and the atrophic Malpighian follicles.

Objective—Zeiss no. 10 (apochromat).

Ocular—Leitz 8 × (periplan.).

Fig. 7.—Photomicrograph (high power view) of a section of the splenic pulp from a case of acute kala-azar showing a large number of phagocytic mononuclear cells packed with the parasites; the sinuses are much dilated.

Objective—Oil-immersion 1/12 inch.

Ocular—Leitz 8 × (periplan.).

Fig. 8.—Photomicrograph (high power view) of a section of liver from a case of acute kala-azar showing enormous enlargement of the Kupffer's cells and their cytoplasm packed with parasites; the hepatic cells which are free from parasites show various grades of fatty change.

Objective—Oil-immersion 1/12 inch.

Ocular—Leitz 8 × (periplan.).

PLATE IV

Fig. 9—The same as figure 8 under much higher magnification showing a single Kupffer's cell with numerous parasites.

Objective—Oil-immersion 1/12 inch.
Ocular—Zeiss Homel 20 mm.

Fig 10—Photomicrograph (low power view) of a section of spleen from a case of 'Bengal splenomegaly' showing an almost complete alteration in the splenic pattern; a much atrophied Malpighian corpuscle may be seen here.

Objective—Zeiss no. 10 (apochromat).
Ocular—Zeiss no 4 (compens.).

Fig 11.—Photomicrograph (low power view) of a section of spleen from a case of 'Bengal splenomegaly' showing the structure of the splenic pulp which consists of dilated sinuses packed with lymphocytes and many large phagocytic mono- and multi-nucleated giant cells

Objective—Leitz 8 mm.
Ocular—Leitz 8 × (periplan)

Fig 12—The same as figure 11 under high magnification showing the contents of a blood sinus; note the numerous giant cells with intense red cell phagocytosis

Objective—Leitz 6a.
Ocular—Leitz 8 × (periplan.).

although hæmosiderin may be demonstrated in fairly large amount by treating a section by appropriate methods.

While so much alteration is going on in the spleen, the liver and bone marrow do not remain idle. The Kupffer's cells of the liver show enormous increase in size and number, their cytoplasm being fully packed with the parasites (plate III, figure 8, and plate IV, figure 9). The hepatic capillaries from which these cells draw their nourishment become dilated and engorged, almost looking like sinusoids. The parenchyma cells may show various grades of fatty metamorphosis but they remain always free from parasitization. Although Rogers (1919) described marked increase in fibrous tissue in the organ in general producing definite cirrhotic changes, the idea of pericellular or multilobular cirrhosis resulting from a chronic leishmania infection can no longer be entertained in view of the histological findings stated above. The bone marrow always takes part in the series of changes. The yellow marrow is more or less completely replaced by a red formative marrow in which one would find not only evidence of intense hæmopoietic activities but also the same type of large mononuclear cells with extensive parasitization.

Thus it will be seen, from what has been stated above, that the enlargement of the spleen in leishmaniasis occurs as a result of a demand on the organ for increased work, viz, the disposal of the infective elements. The peculiar mesenchymal reaction, the increased vascularity, the disappearance of the Malpighian follicles, etc., are only different expressions of how the organ meets the emergency. This also explains why the splenomegaly disappears completely when the organ is relieved of its extra burden of work by dealing with the infective agents by means of specific therapeutic measures.

In addition to the above-mentioned conditions, there is a third variety of splenomegaly which is very common in certain parts of India and particularly in Bengal, and which is also due to a morbid process presumably of an exactly similar character (De, 1932, and *Report of S. A. B. of I. R. F. A.*, 1937). The disease has not yet been definitely classified and for want of a proper scientific name it has been provisionally called Bengal splenomegaly [*Ind. Med. Gaz.*, Editorial (1935) and Connor (1933)]. It is characterized by a very long course, usually with little febrile disturbance except at the beginning. Both the liver and the spleen undergo enormous enlargement. There is always a varying degree of anæmia of a hypochromic microcytic type. Most of the patients die of some intercurrent infection, but a certain number of them develop a portal type of cirrhosis of the liver with terminal ascites. At this stage, these cases resemble the clinical picture of Banti's syndrome. Laboratory examinations fail to reveal the presence of any infective agent of a protozoal or bacterial nature.

In a typical case of this kind, the spleen is much enlarged, the degree of enlargement varying with the duration of the illness. In a long-standing case, the spleen may be found to occupy almost three-fourths of the abdominal cavity, the average total weight being 6-8 pounds. The capsule is thick and areas of marked perisplenitis can often be seen on the surface. During section, a good deal of resistance, sometimes a grating sensation, is felt. In a long-standing case the substance is very firm and cannot be easily broken down, the consistency being tough like that of leather. The trabeculae are very numerous and prominent and one can hardly make out the Malpighian follicles (plate I, figure C). Vascular engorgement is very great in the earlier cases and an idea of its extent may be obtained during splenectomy operations. As soon as the ligature is removed from the hilar veins, an enormous quantity of blood flows out of the organ which subsequently shrinks in size. Under the microscope, the normal structure of the spleen is completely altered (plate IV, figure 10) and it often becomes difficult to recognize the splenic pattern. The Malpighian follicles undergo marked atrophy, being encroached upon by the altered pulp. The sinuses are widely dilated and packed with lymphocytes, large phagocytic monocytes, multinucleated giant cells and a fair number of leucocytes (plate IV, figures 11 and 12). Around the sinuses there remains only a small portion of the actual pulp tissue which is very poor in its vital cellular elements. Both the reticulum and the connective tissue elements are much increased and they are responsible for the firm consistency of the organ. This last feature, however, is only prominent in a case of long duration. In spite of all attempts, no parasite could be detected.

A study of the morbid changes occurring in such enlarged spleens shows that the same factors are at work in the pathogenesis of their enlargement as are met with in chronic malaria and leishmaniasis. There is only one difference, viz, that whereas we know the infective agents which initiate the primary change in the last two conditions, it is still unknown in the other. But from what has been described above, it appears that some as yet undetermined infective agent of a low grade of virulence is at work and the splenic enlargement is only an expression of the sum total of its reactions to such a process.

A STUDY OF TREATMENT OF TETANUS BASED ON A REVIEW OF 38 CASES FROM THE YEAR 1932-1937

By M. G. KINI, M.C., M.B., M.Ch. (Ortho.), F.R.C.S.E.
Surgeon

and

S. VENKATESWARA RAO, M.B., B.S.

House Surgeon,

King George Hospital, Vizagapatam (S. India)

TETANUS as a disease was known to ancient medicine, including Hindu medicine. Hippocrates (460-370 B.C.), the father of modern medicine, described the clinical symptoms accurately. Charaka and Sushruta (900 B.C.?) had also described this condition in Hindu medicine. The transmissibility of this disease to lower animals was demonstrated by Carle and Rattone in 1884. It was Nicolaier of Gottingen who in 1884 first demonstrated in lower animals 'tetanus' by inoculating earth into them. Kitasato in 1889 was the first to obtain the organism in pure culture. Prior to the Great War, only accidental wounds caused tetanus among the civil population and the mortality rate was high. The discovery of the anti-serum of tetanus by Kitasato and Behring has revolutionized the prophylactic treatment of this disease. The prophylactic treatment was put to the acid test in the war with remarkable diminution in the incidence of tetanus cases as a result of wounds. In the early part of the war the incidence and mortality rates were high. Routine administration of anti-serum in every case of gun-shot wound decreased the incidence and mortality rates. Among 2,032,142 wounded, 2,385 developed tetanus giving an incidence of 1.17 per 1,000 wounded (Bruce). The mortality rate of 62.5 per cent in 1914-15 was reduced to 45.9 per cent in 1916-17 and 31.9 per cent in 1918-19 (Choyce, 1932). Though the prophylactic

lactic treatment has been a great success, the problem of treatment of tetanus, once it is established, is not solved. Various methods of treatment from time to time have been advocated with comparative statements in support of the greater success claimed for the respective methods. The results, however, remain far from satisfactory, because as many as 50 per cent die after any improved methods of treatment. Though this mortality rate may be an improvement on the old mortality rates yet it cannot be considered satisfactory. The object of this paper is to show the results obtained by a simple method of treatment followed by the writers in their clinic. It is not claimed that the treatment is ideal, but the results achieved compare favourably with those claimed for more elaborate lines of treatment alleged to be more efficacious. The conditions under which the treatment outlined below was adopted in cases suffering from tetanus were far from satisfactory and far from the ideals of treatment advocated, as it was not possible to ensure the quiet and segregation that is necessary in the treatment of this condition, in our overcrowded wards. The value of this type of treatment became apparent only after tabulating the cases with their results and follow-up.

Out of 4,416 cases admitted in our wards from 1932-1937, 38 were tetanus cases forming 0.86 per cent of the total admissions, i.e., 1 in 116 admissions was a tetanus case. This shows that this disease is common in the civil population of Andhra Desa (India). It is surprising, however, that in spite of the common practice which is found among the village and illiterate folk of treating open wounds with cow-dung as a surgical dressing, there are so few cases of tetanus occurring among them. This is probably due to the fact that the tetanus germ is not usually found in cow-dung. Of the 38 cases that were treated under our care from 1932 to 1937, 33 were males and 5 were females. Most of the cases came from neighbouring villages and had not received any prophylactic treatment at all. There was one case of local tetanus and one case of cephalo-tetanus which are worthy of record.

A Hindu male boy, aged 7 years, was admitted (case 30) with convulsive spasms of both legs coming on every five minutes, on 17th May, 1937, with a history of crushed healed injury of left toe, a month before. A dose of 20,000 units of anti-tetanus serum was administered intravenously with the usual administration of chloral and bromide with marked relief of rigidity of spasms. 10,000 units were given the following day and the boy was subsequently discharged with no recurrence of symptoms, and is keeping perfect health since that time.

The second case, cephalo-tetanus (case 14), was admitted with a history of a scalp wound over the head. No accurate information could be gathered with regard to the incubation period as the patient was having very frequent fits with one-sided facial paralysis and marked lockjaw. His relatives were however certain that he was perfectly healthy prior to the accident. A dose of 40,000 units of anti-tetanus serum was given intravenously and the patient died 15 minutes after admission.

Statement of tetanus cases admitted and treated with the results from 1932-1937

Year and serial number	Age	Sex	Site of injury	Incubation period in days	Duration in days	Condition on admission	Frequency of fits	Local treatment	Dosage of anti-toxin	Cost in rupees	Sedatives used	Result and remarks
1932 1	13	H. M.	No injury	..	2	Poor	Very frequent fits with opisthotonos.	Nil	30,000 units in two doses (i.m.).	15-0	Chloral and bromides.	Died in a day.
2	40	H. F.	Do.	..	2	Do.	Do.	Nil	15,000 units in one dose (i.v.).	7-8	Do.	Do.
3	40	H. M.	Abrasions chest.	?	2	Hamaturia	Spasms every 5 to 10 minutes; conscious.	Nil	15,000 units per day in two doses (i.v.). Total 75,000 units.	37-8	Do.	Refused to stay in the hospital.
4	50	H. M.	Head, over parietal region.	20	10	Fair	Very frequent spasms with opisthotonos.	Healing ulcer dressed.	1st day, 20,000 units in two doses (i.v.). 9 days, 19,500 twice (i.v.m.). 2 days, 10,500 units (i.v.) in two doses. Total 216,500 units.	108-4	Do.	Cured.
1933 5	10	H. M.	Three septic ulcers, hip.	?	2	Moribund	Very frequent with marked opisthotonos.	Ulcers dressed.	One dose of 10,000 units (i.v.).	5-0	Do.	Died within a few hours.
6	Not noted	H. M.	Toe	7	8	Fair	Very frequent spasms.	Wound healed.	8 days, 20,000 units a day in two doses (i.v.) Spasms relieved. Rigidity present. 6 days, 10,000 units a day in two doses (i.v.). 15 days, 5,000 units a day, one dose (i.v.). Total 295,000 units.	147-8	Do.	Cured.
1934 7	40	H. M.	No injury	..	7	Poor	Very severe spasms with opisthotonos, with difficulty in breathing.	Nil	10,000 units (i.v.) statim.	5-0	Do.	Died in a few hours.
8	30	H. F.	After abortion by barber midwife.	12	8	Fair	Frequent spasms	Nil	One day, 20,000 units in two doses in a day (i.v.). 3 days, 10,000 units a day in two doses (i.v.). 12 days, 5,000 units a day in a single dose (i.v.). One day, 1,000 units (i.v.) Total 111,000 units.	55-10	Do.	Cured.

Statement of tetanus cases admitted and treated with the results from 1932-1937—contd.

Year and serial number	Age	Sex	Site of injury	Incubation period in days	Duration in days	Condition on admission	Frequency of fits	Local treatment	Dosage of anti-toxin	Cost in rupees	Sedatives used	Result and remarks
9	33	H. M.	Head	?	..	Poor	Very frequent spasms.	Wound dressed.	1st day, 5,000 units a day, once (i.v.). 2nd day, 15,000 units. 10 days at 20,000 units a day in two doses. 5 days at 10,000 units a day in two doses. Total 285,000 units.	147-0	Chloral and bromides.	Developed dysentery and died. Had recovered from spasms completely.
10	30	H. F.	Abortion by a barber midwife.	?	4	Fair	Do.	..	16 days at 20,000 units twice daily (i.v.). Total 320,000 units.	160-0	Do.	Cured.
1935 11	20	H. M.	No injury	?	5	Do.	Spasms increase after external stimulus. Less after 4 days. Open jaw after 12 days.	..	One day, 40,000 units in two doses (i.v.). One day, 20,000 units in two doses (i.v.). 16 days at 40,000 units in two doses twice daily (i.v.). Total 600,000 units.	300-0	Chloral and bromides. Rectal paraldehyde.	Do.
12	40	H. M.	Do.	?	?	Do.	Marked spasms frequently without opisthotonos.	..	One day, 20,000 units in two doses (i.v.). 9 days, 40,000 units in two doses (i.v. and subcutaneous). Rigidity less after 220,000 units. Able to open mouth—11 days (i.v.) 200,000 Subcutaneous 180,000 Total 380,000	140-0	Chloral and bromides.	Do.
13	16	H. M.	Injection for dysentery, intra-muscular, left shoulder.	9	1	Poor; slight sepsis at site of puncture.	Marked spasms every 2 hours.	Local dressing.	One day, 20,000 units	10-0	Do.	Died in 1 day.
14	50	H. M.	Wound head septic.	?	?	Poor; unable to speak; facial paralysis.	Marked fits with tonic contraction; admitted moribund.	Cleaned and dressed.	40,000 units (i.v.) statim.	20-0	..	Died 15 minutes after admission.

1936 15	4	M. M.	Punctured wound right foot.	6	2	Fair	Very frequent spasms; slight opisthotonos.	Do.	8 days, 40,000 units in two doses (i.v.). 10 days, 20,000 units in two doses. Total 520,000 units.	260-0	Do.	Cured.
16	12	H. M.	Punctured wound foot.	9	6	Comatose between fits.	Very frequent fits with opistho- tonos.	Do.	1st day, 40,000 units in two doses (i.v.). 2nd day, 60,000 units in two doses (i.v.). Total 100,000 units.	50-0	Rectal paraldehyde.	Died.
17	7	H. M.	Shin	10	3	Poor	Very frequent fits	Do.	1st day, 20,000 units in two doses. 2nd day, 60,000 units in three doses. 1 (i.m.), 2 (i.v.). 3rd day, 40,000 units in two doses (i.v.). Total 120,000 units.	60-0	Chloral and bromides. Rectal paraldehyde.	Broncho-pneu- monia. Died.
18	30	H. M.	Wound toe	13	5	Good	Frequent spasms	Do.	6 days, 40,000 units in two doses. 4 days, 20,000 units in two doses. Total 320,000 units.	160-0	Chloral and bromides.	Cured.

i.v. = Intravenous.
i.m. = Intramuscular.

Injury

The following is a list of injuries that were responsible for the onset of tetanus :—

Thorn pricks ..	2 cases	
Head injury ..	4 "	(1 cephalo-tetanus: case 14.)
Intramuscular injection ..	2 "	(1 after anti-dysenteric serum and 1 after sulpharsenol injection: cases 13 and 32.)
Compound fracture	1 case	
Abortion ..	3 cases	
Injuries to toe ..	8 "	(1 was an epileptic: case 31.)
Penetrating wounds sole of foot ..	2 "	
Injury to chest ..	1 case	
Injury to shin ..	2 cases	
Treatment of a painful ear by a quack ..	1 case	
Popliteal wound ..	1 "	
Ulcers of the hip ..	1 "	
Fall in the field with abrasions ..	1 "	
TOTAL ..	29 cases	

Nine cases gave no history of injury, nor could any external evidence of injury be made out. Out of the 5 female cases in the series, 3 developed tetanus after abortion conducted under unhygienic conditions, and all the three recovered: cases 8, 10 and 19. The two cases that occurred after intramuscular injections were fatal; in both there was mild sepsis at the site of puncture.

It is well established from bacteriological examination of the soil that the tetanus bacillus exists in the soil (Gilles, 1937). Experiments conducted in our college laboratory proves the existence of the tetanus bacillus in the local soil (N. G. Pandalai, unpublished). At present in civil practice every casualty section of a hospital is well provided with anti-serum which is used freely wherever there is any doubt of tetanus infection after an injury. No case of tetanus has occurred in cases where anti-serum has been given as a prophylactic measure.

It was very difficult to find out the exact period of onset from the patients, as most of them were illiterate. All the cases were acute in type, admitted with rigidity, opisthotonus, and spasms coming every one to two minutes, and in some cases with longer intervals. The degree of acuteness varied slightly from case to case as noted in the statement appended.

Treatment

Prophylactic.—There are two ways of prophylaxis :

- (1) Passive immunization by anti-serum.
- (2) Active immunization by tetanus toxoid.

In King George Hospital, Vizagapatam, doses from 500 to 1,500 units of anti-serum are given as a routine. The active immunization by tetanus toxoid has not been tried. Herman Gold (1937) concluded from a study of 34 adults that active immunization was not suitable in the

present experience of the general practice, except for military practice and some phases of civil practice only. It is proved, however, by Sneath and Kerslake (1935) that the immunity lasts even after 2 years in persons that received 3 doses of tetanus toxoid. Nattan-Larrier *et al.* (1927) found that efficacy of tetanus toxoid in immunization was actually increased if a bacteriological vaccine, such as T A B, was injected at the same time.

Curative.—Various forms of treatment have been recommended. According to H. Meyer and Ransom (1903) and Aschoff and Robertson (1915) the toxin is secreted locally in the infected region and ascends along the lymphatics of the nerve to the corresponding section of the spinal cord to the anterior horn cells. From here it passes through lymphatic spaces to higher centres. A part of the toxin is conveyed by the blood stream and another part is bound and neutralized by tissue cells which are not themselves susceptible to the toxin. Wassermann and Tekaki (1899) have proved, however, that the toxin gets fixed in the brain substance, having a particular affinity for it. An intact nerve bundle is therefore necessary for the spread of this disease. Accordingly prevention of the spread of the toxins was attempted from the original lesion by section of the connected nerve. This method, however, has proved both difficult and unreliable. Leslie Cole (1936) advised intravenous administration of 200,000 units of anti-toxin followed an hour later by surgical treatment of the wound. Abercrombie (1936) from his experience in the Great War was convinced that severe tetanus associated with extensive wounds recovered if treated with large doses of anti-toxin, provided that no surgical interference of the wound was permitted.

Is anti-tetanus serum useful as a curative agent?

Huntington, Thompson and Gordon (1937) analysed 642 cases and found a mortality rate of 65.3 per cent in untreated cases as compared with 58.6 to 66.1 per cent in the treated cases. They concluded that the effect of anti-toxin treatment could not be great. We believe, however, with Yodh and others that anti-toxin treatment is the only rational form of treatment at present available and certainly has helped many cases to recovery. Clinical observation has shown that the anti-toxin is of great value in the cure of spasms of this disease. Case 30 illustrated the effect of the anti-toxin in a boy with local tetanus, who after the administration of 30,000 units was free from spasms, was discharged cured in 3 days' time and has remained perfectly fit. Case 38 received 20,000 units per day in 2 doses intravenously daily. Eight days before discharge anti-toxin administration was stopped; during this period of cessation of the administration of anti-toxin during convalescence severe spasms of the adductors of both hips and flexors of the knee developed causing him severe pain resulting in sleeplessness, even though the

jaw and trunk muscles were perfectly relaxed. On repeating the dose for 2 days more the spasm was relieved and he was discharged cured two days after and he is now keeping perfectly fit.

Intravenous versus intrathecal route.—Weed (1932) has shown that the cerebrospinal fluid comes mainly from the choroid plexus, only a small amount passing out along the perivascular spaces to the sub-arachnoid space. From there it travels through the arachnoidal villi into the venous sinuses. The fluid introduced into the theca will therefore tend to pass into the vein by the arachnoidal villi and will not come at once into close contact with the nervous tissues. All parts of the brain are richly supplied with blood vessels and capillaries. Anti-toxin therefore could reach these nerve cells more quickly when given directly into the vein than if it were first injected into the spinal theca and then absorbed into the venous sinuses through the arachnoidal villi. Florey and Fildes (1927) compared the two routes in rabbits and found that the intrathecal route had no advantage over the intravenous route. Cole and Spooner (1935) studied the fate of injected anti-toxin in 4 patients, each of whom had a single initial dose of 200,000 units. The result of this investigation indicated that 7 days after injection there were 10 units of anti-toxin per c.cm., i.e., a total of 50,000 units still left in the circulating blood and at the end of 14 days between 3 and 5 units per c.cm. Yodh (1937) showed by his experiments on guinea-pigs that in tetanus patients no toxin is found in the cerebrospinal fluid but only in the blood stream. Anti-toxin therefore in the cerebrospinal fluid can only act through its absorption into the blood stream. In intrathecal administration either by lumbar puncture or cisterna puncture (Yodh) there are difficulties in the administration through this route on account of the marked rigidity which is present in these tetanus cases. An anæsthetic therefore is universally required in adopting this method. Moreover, intrathecal administration of serum is not without its dangers. The chief danger experienced by one of the writers (M. G. K.) while working with Colonel (now General) Bradfield in the General Hospital, Madras, was the complication of hyperpyrexia which was fatal in two instances in spite of careful nursing. Having had bad experience with this method, it was not tried in this series even though concentrated serum was available. From a study of the cases recovered and from the experiments of Spooner it becomes quite apparent that injections of large initial doses of the serum are not necessary. The highest daily routine dose was not more than 40,000 units administered morning and evening in two doses by the intravenous route, whenever possible. In four cases 80,000 units per day were given. The average daily routine dose was 20,000 units per day given in 2 doses morning and evening. Large doses in children are not without danger. Two children developed broncho-pneumonia after the administration

(cases 17 and 24). Dufour advocated administration of an anæsthetic, preferably chloroform or ether, for half an hour twice a day to displace the toxin from the nerve cells, and a simultaneous administration of the anti-toxin by the intravenous drip method, so as to prevent the liberated toxin from being absorbed. Fraenkel (1936) suggested surgical treatment of the wound first under general anæsthesia, then a lumbar puncture followed by injection of anti-serum with subsequent elevation of pelvis, and finally injection of the anti-serum subdurally and bilaterally through small trephined apertures over both hemispheres. The idea was to remove as much toxin as possible with the cerebrospinal fluid and replace the fluid with anti-serum which would neutralize the toxin subsequently displaced into the cerebrospinal fluid from the cerebral substance. It is our opinion that it is a drastic form of treatment. Yodh (1937) obtained encouraging results by the combined intrathecal (cisterna route), intravenous, and intramuscular methods. Perfect relaxation is necessary before introducing the needle into the theca to overcome marked rigidity of the muscles of the back, with or without opisthotonus, so commonly found in tetanus cases. While administering a general anæsthetic, such as chloroform or ether, in the induction stage, there is an exaggeration of all reflexes with increased rigidity of muscles; in cases of tetanus it had been the experience of one of the writers (M. G. K.) that this exaggeration of reflexes and rigidity was a distressing feature, causing difficulty in breathing with consequent altered circulation, and was attended with great danger unless great care was taken during the induction stage. Recent reports show that control of spasm by curare and curareine is not without danger of respiratory and circulatory failure.

Our method

In cases where the wounds were still raw no surgical interference was done except the provision of free drainage. Our aim has been not to break the inflammatory barriers but to release pus under pressure and allow air to reach the damaged tissue. A routine administration of 20,000 units per day in two doses morning and evening for adults, by the intravenous route, was the method of choice. In some cases 40,000 units a day and in 4 cases 80,000 units a day were given. From a review of the results, it becomes apparent that these large doses are unnecessary. In some cases where the intravenous route was difficult, the intramuscular and subcutaneous routes were adopted. This administration was continued every day until the spasms disappeared. 10,000 units of anti-serum were drawn into a 20 c.cm. syringe containing normal saline and slowly injected intravenously. On a review of the cases the results show that this simple method is no less efficacious than the methods hitherto advocated. Until now no bad effect has been noticed except in the case of two

children who developed broncho-pneumonia and died after the administration of large doses of anti-toxin. After the experience gained from the tabulated results smaller doses of anti-toxin were used from the beginning of the year 1938.

respectively. The figures show that the mortality rate of our series in which a simple form of treatment by anti-toxic serum and sedatives was adopted compares favourably with those of other workers employing more elaborate methods of treatment.

Mortality rates

	Authors	Yodh's (1937)	Leslie Cole (1937)	John W. Klopp (1936)	Huntington and others (1937)
Cases ..	38	438	30	56	642
Cured ..	19 (50 per cent)	49.4 per cent	56.6 per cent	27 per cent	..
Died ..	18* (47.37 per cent)	50.6 † per cent	43.3 per cent	72 per cent	58.6 to 66.1 per cent

* One discharged at request.

† Including 15 discharged at request.

Sedative treatment.—Chloral and bromides in doses of 30 and 60 grains respectively were given by the mouth in 3 doses daily in adults and correspondingly smaller doses in children. In some cases where it was difficult to administer these by the mouth rectal administration of 4 drams of paraldehyde in 10 ounces of saline by the drip method was substituted. We are completely satisfied with the sedative action of these drugs. The ideal method of treatment of these cases in sound-proof and light-proof room was not possible as no such special accommodation was available.

Results

We believe that it is fallacious to compare results of one group with another. Groups of

Mortality rate excluding deaths within 24 hours

Authors	Yodh (1937)	Leslie Cole (1937)
18.42 per cent	29.4 per cent	22.7 per cent

The ages of 3 patients are not known. The incidence of tetanus appears to be less after 30 years, but the mortality rate is very high after this age.

From the table it will be seen that the shorter the incubation period the worse the prognosis. The best prognosis is after an incubation period of 10 days. The mortality of 77.7 per cent among those cases which gave no history of injury is significant. Our results in this respect are in agreement with those of Yodh.

(1) Incidence of age

	Less than 10 years	11-20	21-30	31-40	Above 40
Number of cases	9	8	9	6	3
Cured ..	5 † (55.6 per cent)	5 (62.5 per cent)	5 (55.6 per cent)	1 (16.6 per cent)	1 (33.3 per cent)
Died ..	4* (44.4 per cent)	3 (37.5 per cent)	4 (44.4 per cent)	4 ‡ (83.3 per cent)	2 (66.7 per cent)

* Two children each aged 7 years died of broncho-pneumonia.

† One of this group was a case of local tetanus.

‡ One was discharged at request and not shown as died. One died after 16 days of dysentery, after complete cure of the spasms (case 9).

(2) Incubation period

	1-5 days	6-10 days	Above 10 days	No history of injury	History of injury available but no history of incubation period
Number	6	7	10	9	6
Cured ..	2 (33.3 per cent)	4 (57.1 per cent)	9 † (90.0 per cent)	2 (22.2 per cent)	2 (33.3 per cent)
Died ..	4	3	1	7	3*

* One died of dysentery after 16 days, after complete cure of spasms. One was 'discharged otherwise' and is not shown among the 'died' cases.

† One case cured was a local tetanus.

cases of the same acuteness must be selected before making any comparison. However, a comparative statement is made showing the respective mortality rates.

One of our patients died of dysentery after progressing 16 days satisfactorily, and two boys died of broncho-pneumonia after 3 and 2 days,

Period of onset

As explained in the earlier part of this paper, the period of onset could not be elicited in our series, as the patients were illiterate and could not give correctly the date of first occurrence of symptoms. Yodh (1937) observes that if the period of onset was 3 days or over there were

greater chances of recovery even with short incubation period. We are not able to testify to this observation, because we could not get this information correctly.

Duration of great prognostic value

Except one case of local tetanus, 37 cases were all acute with generalized spasm, and the patients could give the duration of symptoms. From the time the symptoms started to the time they were admitted into the hospital was taken as the duration and an attempt was made to foretell the prognosis from this. Out of 18 deaths, the duration of 2 cases was not known: of this one patient was admitted moribund and died 15 minutes after admission (a case of cephalo-tetanus). Out of the 16 deaths, 12 deaths were in those in whom the duration was only 3 days or less, which works out to a mortality of 75 per cent. Four cases died with duration of 5, 6, 7 and 8 days, respectively. The mortality rate after 3 days is 25 per cent. Thus prognosis may be said to depend on the duration, being good after 3 days, better after 5 days, and excellent after 8 days.

Economic value of the treatment

With the exception of 2 cases, who received intramuscular injections, the rest of the patients that were admitted were from the poorer classes, whose wage-earning capacity was not more than Rs. 10 (£0-15-0) a month. In adopting the treatment in a general hospital for this condition the cost of anti-serum has to be seriously considered, apart from the question of diet, nursing and medical attendance. It requires on an average Rs. 240-14-5 (£28-10-1) to cure a patient. The highest was Rs. 520 (£39) and the lowest cost was Rs. 55-10-0 (£4-3-5), excluding the case of local tetanus which cost only Rs. 15 (£1-2-6). This is based on the value of anti-toxin which is supplied at Rs. 10 (£0-15-0) for 20,000 units, and the exchange value of one rupee is calculated at Re. 1 = £0-1-6. The average amount of money that was spent on serum on all those that died was Rs. 38-5-4 (£2-17-6). The highest amount spent was Rs. 147-0-0 (£11-1-3), and this was for the unfortunate patient that died of dysentery on the 16th day after recovering from the spasms completely (case 9), and the lowest cost was Rs. 5 (£0-7-6), excluding a case which was discharged on request. It is therefore evident that the cost of treatment of tetanus, even taking only the value of serum into consideration, is very expensive and is beyond the means of the type of patients admitted. The average duration of stay of a patient was 22 days, and the longest period was 42 days. The complications that occurred during the treatment were as follows:—

(1) Difficulty in the administration of diet. In several cases nasal feeding had to be resorted to when the spasms were severe.

(2) Broncho-pneumonia occurred in two cases.

(3) Dysentery occurred in two cases during convalescence, one patient died and one recovered. This was due to giving of unauthorized food by the relations.

(4) Parotitis occurred in one case.

Conclusion

From a review of all the available methods of treatment it becomes clear that to evaluate a treatment in the cure of a disease the following conditions must be satisfied:—

(1) The treatment must be simple and should be capable of being practised by the average practitioner.

(2) Small percentages of improvement in the mortality rate should not be taken as a criterion denoting efficiency in the treatment.

(3) The cost of treatment must be within the means of an average man who suffers from this disease.

Taking all these three conditions together, the treatment of tetanus is still not satisfactory.

Summary

1. A review of 38 cases of tetanus and a study of the principles and modes of treatment was made.

2. A case of local tetanus was described. Among the forms of injuries that followed, three occurred after abortion and two after intramuscular injections. Nine patients gave no history of injury; one was an epileptic.

3. The simple mode of treatment followed by the authors was described and mortality rates compared.

4. In assessing prognosis besides incidence of age, incubation period, and period of onset, 'duration' is suggested to be of great prognostic value.

5. The economic value of the treatment and average period of stay in the hospital was also discussed.

MAPHARSIDE IN THE TREATMENT OF SYPHILIS—A CLINICAL STUDY

By R. V. RAJAM, M.B., M.S., M.R.C.P.
Venereal Specialist, General Hospital, Madras
and

N. VASUDEVA RAO, M.B., B.S.
Honorary Assistant Surgeon, Venereal Department,
General Hospital, Madras

MAPHARSIDE is one of the latest organic trivalent arsenical compounds introduced in the therapy of syphilis. An increasing volume of literature about its therapeutic and toxic effects has been published, particularly in American medical journals. This drug, whose name is derived from the abbreviations of the initials of the chemical name meta-amino-para-hydroxy-phenyl-arsine oxide, is generally accepted as the actively treponemicidal cleavage product of arsphenamine and neo-arsphenamine. According to the studies of Ehrlich, Bertheim, Voeghtein and others arsphenamine and neo-arsphenamine are not treponemicidal as such, but owe their curative property to their being oxidized in the human body into the actively parasitocidal arseno-oxide. Such a product prepared *in vitro* is mapharside.

Tatum and Cooper (1934) in their experimental studies of mapharside in rabbit syphilis came to the following conclusions:—

1. Mapharside is a pure chemical preparation the purity of which can be determined by chemical methods. The arsphenamines and neo-arsphenamines on the other hand are chemical mixtures and consequently the toxicity and therapeutic values may vary with each batch.

2. The drug is comparatively stable and becomes less toxic on long exposure to air.

3. In rabbit syphilis, the effective therapeutic dose of mapharside is one-fiftieth to one-thirtieth of that required of neo-arsphenamine.

4. The chemo-therapeutic index (ratio of maximal tolerated dose to minimal curative dose) was found to be higher than that of any other anti-syphilitic agent known to them. On these grounds they advocated a clinical investigation in human syphilis. Since then a number of clinics in America with the lead by Foerster and his associates (1935) have reported favourably on this drug in the treatment of syphilis.

Mapharside is a dry, hygroscopic stable powder readily soluble in water. It contains 29.01 per cent of metallic arsenic, approximately the same as that of the arsphenamines. In the proportion of 4 milligrammes per cubic centimetre of distilled water, the solution is isotonic.

The solution is slightly acid and does not undergo any toxic change on standing. This is of great advantage in clinics where a large number of patients have to be injected in succession. The solution on prolonged exposure and agitation for hours may gradually darken. A large bulk dose may be dissolved in the required quantity of distilled water and administered successively to patients over a period of 2 or 3 hours. We have even kept the solution overnight and administered it next morning without any harm, though the therapeutic effect seems to be lessened after 8 hours. In all cases, the drug is given intravenously only. To avoid the occurrence of venous spasm and pain in the arm, the drug after solution is kept standing for a few minutes and should be injected fairly rapidly in 15 to 20 seconds. The effective therapeutic dose of mapharside being much less than that of neo-arsphenamine, a smaller quantity of arsenic is introduced into the body. The adult dose of mapharside varies from 0.04 gm. to 0.06 gm. In the case of females, an initial dose of 0.03 is recommended.

In the venereal clinic of the Government General Hospital we had been using one of the older trivalent preparations of arsenic in the routine treatment of syphilis for a number of years and it is our experience that the tolerance of the average South Indian patient of the poor hospital class to this drug has been unsatisfactory. Toxic side reactions, particularly of the severe and often fatal type, have been more frequently observed than the statistics of European clinics show. We have satisfied ourselves that this increased frequency of toxic reactions to the older preparation is not due to individual dosage, to the interval between injections, or to the total dosage employed. It is well known that neo-arsphenamine preparations vary in their toxicity and therapeutic effectiveness from one brand to another and from one lot to another lot of the same preparation. It is not known definitely what changes these extremely unstable products of varying chemical purity undergo under tropical conditions of storage and usage.

The new preparation, mapharside, was reported to be free from the severe reactions, and was deemed to be equally therapeutically effective, by a number of American medical writers. We decided to substitute mapharside for neo-arsphenamine in the routine treatment of syphilis. A complete evaluation of the drug cannot be attempted in this paper as the material available does not lend itself to satisfactory statistical long range observation and record.

The results published in this article cover a study of mapharside in the treatment of syphilis of adult and adolescent patients of both sexes over a period of nearly a year. Children were excluded from this treatment. Notoriously inadequate treatment is the rule rather than the exception, as the majority of the patients default with the healing of clinical lesions. The tracing of defaulters is a matter of great difficulty.

Yodh, B. B. (1937). *Brit. Med. Journ.*, i, p. 855.

False names, false addresses, the ignorance and the apathy of the average venereal disease patient, the fact that more than half the syphilitic patients attending the clinic belong to the itinerant floating population of the city who trek away to their homes in the rural parts of the Presidency and are heard of no more, these constitute and offer insuperable obstacles to any regular follow-up of these patients, the majority of whom probably continue to be in an infectious state. The unsatisfactory state of affairs may be gathered from the fact that in one year from June 1937 to June 1938, 1,000 patients with syphilis had attended the venereal clinic and had received only 5,650 injections of mapharside between them, an average of 5.65 injections per patient. In spite of such handicaps, it is proposed to offer some remarks on this drug with the available records. Of the 1,000 cases of syphilis 798 were males and 202 females. The ages of the patients varied from 14 to 60, the majority being between 18 and 25. The following table gives the classification:—

	Males	Females	Total
Total number of cases ..	798	202	1,000
Primary syphilis ..	227	7	234
Early, secondary syphilis ..	287	51	338
Late benign syphilis ..	73	36	109
Latent syphilis ..	132	86	218
Congenital syphilis ..	3	6	9
Yaws (mostly tertiary) ..	10	5	15
Neurosyphilis (meningovascular) ..	8	1	9
Cardiovascular syphilis ..	1	Nil	1
Total number of injections of mapharside administered	4,382	1,268	5,650

Of the 1,000 cases, only 127 males and 43 females completed one or more courses of injections (one course consisting of 10 injections of mapharside totalling 400 milligrammes). At the commencement of this study, a selected number of patients with syphilis in different stages were admitted into the hospital and treated with mapharside only, in order to assess the spirillicidal, the clinical and the tolerance properties of the drug without the disturbing effect of bismuth. After a satisfactory appraisal of the drug, the combined treatment with mapharside and bismuth was given to almost all the patients in this review. The initial dose for an adult male was 0.04 gm. and 0.03 gm. for the adult female. In a number of male patients, the maximum single dose of 0.06 was tried in the second and subsequent injections and found to produce rather severe minor toxic reactions, such as vomiting, fever, and gastro-intestinal upset and hence, the initial dose of 0.04 gm. or 0.03 gm. was adhered to and repeated in the subsequent injections in most of the patients. In early infectious cases the first four injections were given at 4-day intervals and the subsequent doses once a week.

Spirillicidal effect of mapharside

The effect of a single dose of mapharside (0.04 gm.) was studied in 15 cases of dark-ground-positive primary syphilis. The dark-ground examination became negative to *Spirochaeta pallida* within 18 to 24 hours after the injection in 14 cases. In one case, the spirochaetes did not disappear, though they seemed to be degenerating for 72 hours. The drug therefore is deemed to satisfy one of the important conditions of therapeutic effectiveness, in that it is able to destroy surface spirochaetes in early lesions as rapidly as the older trivalent arsenicals.

Effect on the clinical lesions

The response in 50 cases of primary chancre was noted. The sores healed on the average after 2 to 5 injections. The minimum number of injections required for healing was 2 and the maximum was 9. The response was quicker in the case of primary syphilis with a positive Wassermann reaction than in sero-negative cases.

Forty-six cases of secondary syphilis were observed for their response to mapharside. The eruptions involuted on an average after 3 to 6 injections. The minimum was 3 and the maximum was 10. The pigmentary scars left after the involution of the larger papular syphilides disappeared only very gradually, in the course of a few months, and after 2 or 3 courses of the treatment.

The response of late benign syphilitic lesions to mapharside was equally satisfactory. In this study, 15 cases of tertiary yaws of skin and bone were included and they reacted to mapharside as satisfactorily as syphilitic lesions. Two cases of leuco-melanoderma, a late secondary or tertiary degenerative stigma of syphilis, affecting the palms and soles and parts of the face and the neck, responded to two courses of mapharside and the affected skin assumed almost normal colour and texture. We are reporting these two cases particularly because our previous experience in the treatment of this distressing condition with neo-arsphenamine was very disappointing.

A small number of pregnant women with active and latent syphilis were treated with mapharside with beneficial results. The treatment was continuous throughout the period of pregnancy and many of them stood the therapy extremely well. In two cases, which were followed, live full-term healthy children were born, without any clinical, radiological or serological evidence of syphilis. No cases of early congenital syphilis in infants and children were treated with mapharside. The cases of congenital syphilis included in this study were adolescents, with either stigmata or tertiary manifestations of the infection. In the number included, a few were probably cases of yaws. In these cases, the clinical response of active lesions was as rapid as in those of acquired syphilis.

There were 9 cases of neuro-syphilis, all of them of early meningo-vascular type and neuro-relapses. In this type of case we have found mapharside, as well as the other trivalent arsenicals, distinctly inferior and slower in therapeutic effect to tryparsamide and pyrexial therapy.

Effect on the serological reaction

An accurate evaluation of the drug on the serological reaction of the blood requires long-range treatment and observation, and it is unfortunate that the material available does not lend itself to such a purpose. From the few cases which have had adequate treatment controlled by blood tests, it is inferred that the change in the serology takes place more slowly with mapharside than with older neo-arsphenamine drugs. Far from this being a disadvantage it has the merit of inducing the patient to hold on to the schedule of treatment laid down for a longer period than he would otherwise be tempted to do.

Toxic reactions

The toxic effects of arsenical therapy are usually classified as immediate and minor, delayed and serious. We have attempted below a comparative study of the relative incidence of the toxic reactions by mapharside and one of the older trivalent preparations on 1,000 cases of syphilis in all stages treated with each drug:—

	Mapharside	Neo-arsphenamine
Total number of injections given.	5,650	6,500
Immediate and minor reactions—		
Fever ..	149	64
Headache ..	13	8
Gastro-intestinal upset (vomiting and diarrhoea).	19	5
Nitritoid reactions ..	Nil	8
Fainting ..	5	Nil.
Pain in abdomen ..	1	Nil.
Itching ..	33	67
Mild erythema ..	7	10
Urticaria ..	1	5
Herpes ..	6	12
Herxheimer's reaction	8	2
Vein spasm ..	7	Nil.
	249	181
Delayed severe reactions—		
Exfoliative dermatitis	Nil	12 cases severe and 7 mild.
Jaundice ..	6	10
Encephalitis ..	1 (fatal)	5 (fatal)
Agranulocytosis ..	1 (fatal)	1 (fatal)
	8	35

As has been observed by others, the immediate reactions of mapharside therapy seem to be more frequent than those of neo-arsphenamine. But most of these reactions were mild, evanescent and occur during the first or second injections. During the first two or three months of clinical trial with this drug the maximum dose of 0.06

gm. was administered to many patients as an experimental measure and the larger incidence of immediate reactions may be due to this fact. The absence of nitritoid reactions after mapharside is a special feature to be noted. The cutaneous reactions, itching, erythema, urticaria, herpes were all mild temporary manifestations and treatment was continued with mapharside after a few days or weeks without any recurrence or evidence of increased toxicity. The so-called Herxheimer's reaction or exacerbation of the clinical condition was observed more frequently after mapharside than after neo-arsphenamine and that too only in early syphilis. The occurrence of venous spasm is a unique feature of mapharside therapy and unknown in the treatment with the older drugs. Immediately after an injection, the patient complains of pain shooting up and down the arm and sometimes it is so severe that he cries out. The pain lasts for $\frac{1}{2}$ to 2 hours and is greatly relieved by the application of ice. The venous spasm and the pain can be completely avoided by rapid injection in 15 to 20 seconds and by allowing the solution to stand for a few minutes before administration. When we come to consider the delayed reactions, the distinct superiority of mapharside may be clearly seen. Exfoliative dermatitis, the *bête noire* of the syphilologist, with its weeks of utter misery, ill health, hospitalization and its frequently fatal termination, has been conspicuously absent in the 1,000 cases treated with mapharside in contrast to its high incidence in the other 1,000 treated with neo-arsphenamine.

There were 6 cases of jaundice in the mapharside series, 5 males and 1 female. All the cases were mild and cleared up in 3 to 4 weeks with cessation of the drug and expectant treatment. It is difficult to assess the rôle of mapharside in the causation of jaundice in these cases. The van den Bergh reaction of the blood showed—

Direct immediate positive in 3 cases.

Direct biphasic positive in 2 cases.

Indirect faintly positive in 1 case.

Four cases occurred after 8 injections of mapharside, 2 after 20 injections. As regards the interval between the last injection and developing of jaundice, it was 1 week in 3 cases, 2 weeks in 1 case, 2 months in 1 and 3 months in 1. Four cases of jaundice occurred in the months of April and May, 1 in February, and 1 in July. It is possible that the majority were cases of ordinary catarrhal jaundice and the larger number occurring in April and May might be part of an epidemic of jaundice prevalent in the city.

There were two deaths from mapharside therapy—one caused by encephalitis and the other by granulocytopenia. These unpredictable complications of arsenical therapy have not till now been reported with reference to mapharside. These rare reactions are probably attributable to a personal idiosyncrasy.

Encephalitis

This complication occurred in a male patient, aged 47, with sero-positive primary syphilis. He was given two injections of 0.04 gm. mapharside at an interval of 5 days. Twenty-four hours after the second injection he was admitted with high fever and mental confusion. Within a few hours he became comatose. Examination showed a generalized rigidity of all the limbs, small irregular sluggishly reacting pupils, exaggerated tendon jerks, extensor plantar response, a rapid pulse and hurried respiration. In spite of repeated lumbar puncture, adrenaline injection, oxygen inhalations, etc., the patient progressively and rapidly became worse and expired after 72 hours. A post-mortem examination of the body did not reveal any gross changes except a full and engorged condition of the vessels on the surface of the brain.

Granulocytopenia

This condition happened to a male patient, aged 32, with sero-positive primary syphilis. He was given 5 injections of 0.04 mapharside at intervals of 5 days. Four days after the last injection he was admitted with high fever (104.2°F.) and pain in the gums. Examination revealed swollen, inflamed gum margins. Within 24 hours of admission the mucous membrane of the gums, the mouth, and the throat showed rapidly spreading sloughy ulceration with bad fetor and salivation. A complete blood examination revealed marked leucopenia with no other abnormality. The white blood count was 1,250 with a total absence of granulocytes. The patient looked extremely ill, was unable to swallow or breathe freely. Nuclein injections four hourly campolon daily, and glucose twice daily were administered. The temperature was controlled by hydrotherapy. The patient seemed to rally a bit for 1 or 2 days and then became progressively worse and died of septic pneumonia on the tenth day of admission. There was slight bleeding from the gums and the soft tissues of the neck on either side of the jaw became swollen and infiltrated. He developed a terminal jaundice. One peculiarity we noticed in this case was that, while the clinical condition was getting worse, the daily leucocyte count was showing improvement with the appearance of granular leucocytes. The last total count 24 hours before death was 7,400 with 84 per cent of neutrophil leucocytes. Grave as these complications are, in the treatment of syphilis, they were found to be more frequent with the '914' preparations.

Summary

1. The results of the use of mapharside in the treatment of 1,000 patients suffering from syphilis during a one-year period at the venereal clinic, Government General Hospital, are presented.

2. A complete statistical summary of all the results is not attempted.

A PROBABLE CAUSE OF THE DIFFICULTY OF TREATING CHRONIC AMOEBIC INFECTION IN THIS COUNTRY

By H. GHOSH, M.B., M.S.P.E. (Paris)

Director, Department of Bacteriology, Indian Institute for Medical Research, Calcutta

COLONEL CHOPRA *et al.* (1934) showed in a paper on the treatment of intestinal amoebiasis that it was an extremely difficult problem to cure amoebiasis completely. Repeated courses of emetine, combined with yatren, stovarsol, carbarsone and kurehi had failed to eradicate amoebæ from the colon. This is a common experience of almost all clinicians

(Continued from previous column)

3. The rapidity of the disappearance of the spirochaetes from surface lesions and the clinical response of the lesions themselves are noted as a measure of the effectiveness of the drug. In these respects mapharside is comparable to the older drugs.

4. The speed of reversal of the serological reaction of the blood could not be accurately assessed, though it is our impression that with mapharside the reversal seems slower than with neo-arsphenamine.

5. A comparative study of the toxic reactions, immediate and delayed, caused by mapharside and neo-arsphenamine is attempted.

6. The immediate minor reactions were more frequent with mapharside than with neo-arsphenamine. With mapharside the nitritoid crises were conspicuous by their absence. There was not a single case of exfoliative dermatitis due to mapharside, and the other delayed reactions were much less frequently observed than with neo-arsphenamine. Two deaths following mapharside therapy are recorded.

Conclusion

Mapharside appears to be a distinct refinement in arsenical therapy over the older trivalent drugs. The drug is of definite chemical composition which ensures a uniform purity in the samples. Its stability and non-toxicity in solution is a great advantage in the mass and institutional treatment of syphilis. The therapeutic unit dose of mapharside is about 1/10 that of neo-arsphenamine preparations, and hence less arsenic is introduced into the body. The drug is less toxic in therapeutic doses and better tolerated. None of the serious eutaneous symptoms of intolerance that occur with the older trivalent preparations have been encountered in the treatment with mapharside.

who have the opportunity of observing their patients for a long period. One medical man practising in a *mofussil* town told us that a patient of his, suffering from occasional attacks of amœbic dysentery, had five courses of emetine (each consisting of 6 injections of 1 grain emetine hydrochloride, stovarsol, carbarsone, and kurchi-bismuth-iodide) within a period of two years, yet he could not cure the patient. After each course the patient apparently got well but the condition recurred a few weeks after stopping the treatment. The only explanation of such failure so far adduced was that the amœba got resistant to specific chemotherapeutic drugs.

Since our work (Pal and Ghosh, 1937) on the reaction of stools with relation to fermentation in the intestines and subsequent report by Pasricha *et al.* (1938), we began to wonder whether the constantly acid reaction of the stools of the people of this country, who take much rice or flour and sweets, could have any influence in making the amœbæ resistant to treatment by specific chemotherapy. It is generally known that acid reaction of stools favours the life and growth of *Entamœba histolytica*.

On this hypothesis we treated three cases of chronic amœbiasis, whose stools were highly acid to litmus, with one course of 6 injections of 1 grain emetine followed by oral administration of freshly prepared liquid extract of kurchi for 12 consecutive days while the patients were kept mainly on protein diet with a restricted amount of carbohydrate in the form of porridge and *chapati*. The stool turned alkaline after 48 hours. The restricted diet was enforced in each case for four weeks and the patient was advised to test the reaction of the stool daily with litmus paper. The restriction of diet was lifted after four weeks, but the patients were instructed to avoid rice and sweets as much as possible. We explained to them that if the stool turned acid we should not be held responsible for the recurrence of symptoms. Two of these patients had been suffering from fermentation almost every day and occasional attacks of dysentery for a period of three years. Each had two courses of emetine, stovarsol, kurchi-bismuth-iodide, or liquid extract of kurchi with only temporary relief. The other case had had the same complaints for one year and a half and had taken two courses of emetine (each consisting of 6 injections of 1 grain of emetine), one course of carbarsone, and liquid extract of kurchi. This latter patient had chronic staphylococcal eczema on the skin of both legs which disappeared during the previous courses of treatment of amœbiasis but reappeared after a few weeks. One patient has been under our observation for 11 months, one for 8½ months and the other for 6 months. During the period of observation several examinations of the stools of each were made; up to the time of writing all the three patients were free from amœbæ. The patients had been following our instructions regarding diet,

ON THE INTRA-UTERINE INFECTION OF THE FŒTUS WITH *LEPTOSPIRA ICTEROHÆMORRHAGIÆ*

By B. M. DAS GUPTA

(From the Department of Protozoology, Calcutta School of Tropical Medicine)

OPINIONS differ with regard to the transmissibility of leptospira from the mother to the embryonic guinea-pig. Thus, Costa and Troisier (1916) reported that leptospiræ could penetrate through the placenta as shown by the transmission of infection by inoculation of the amniotic fluid. However, Buchanan (1927) criticized these observations on the ground that the presence of blood in such circumstances cannot be entirely ruled out.

Takagi (1927) found spirochætes in the placenta of guinea-pigs infected with Weil's

(Continued from previous column)

though they said that it was very hard on them to avoid rice and sweets. The general health of all these patients has greatly improved.

Of course, no positive deduction can be drawn from the three cases shown above, but it seems to us that this is a line of investigation worth continuing.

It is, therefore, our suggestion that in treating cases of chronic amœbiasis strict attention should be paid to the adjustment of the diet in such a way as to keep the reaction of the stool alkaline. Rice, sweets and excessive quantity of other carbohydrates tend to make the stool highly acid.

Alkali by mouth can change the reaction of the urine but has little influence on the reaction of stools. Increased meat and fish diet and diminution of the quantity of carbohydrates invariably make the reaction of the stool alkaline. Change to *atta* from rice also changes the reaction of the stool from acid to alkaline.

[Note.—As the writer says 'no positive deductions can be drawn from the three cases'. There are many reasons for this; nowhere is any mention made of the finding of amœbæ in these patients' stools although the cases are labelled 'amœbiasis'. 'During the period of observation several examinations of the stools of each were made' with negative findings, but how many and when? There is therefore neither evidence of amœbiasis nor of its cure. The clinical evidence, however, seems to be clear, though there is nothing to indicate that it was not the change in diet *per se* that caused the improvement. Nevertheless, we consider that this short note is a useful contribution and worth publishing in order to draw attention to an aspect of this difficult problem, the cure of chronic amœbiasis, which has not received sufficient attention hitherto. The diet usually given in amœbiasis would tend rather to increase than decrease the acid reaction of the stools.—EDITOR, I. M. G.]

disease, but the organisms could not be detected in the foetuses. It was found that the spirochaetes had been taken up by ciliated cells and other tissues on the outside of the embryo which seem to protect the foetus from the invasion from the maternal body.

Hiyeda (1927) records a case of abortion of a 4-months-old foetus by a woman suffering from Weil's disease. Although leptospiræ could not be detected in the tissues of the foetus, yet the author argued that the foetus had been infected.

Saenz (1929) inoculated a pregnant guinea-pig with leptospiræ and 5 days later removed the placenta and the foetus. The guinea-pigs inoculated with the emulsion of the foetus and placenta died of leptospiral infection after 7 and 13 days, respectively. A second guinea-pig was infected 6 days before the birth of 2 young ones both of which showed definite evidence of leptospiral infection.

With a view to arriving at a solution to this controversial problem 7 guinea-pigs in varying stages of pregnancy were inoculated each with 3 c.cm. of a virulent culture. One animal in an advanced stage of pregnancy gave birth to 2 live and well-developed young ones about 30 hours after the infective inoculation. Peritoneal fluid and blood of these young ones were examined at birth and thereafter once a day for 5 days. The results were always negative, but on the 6th day the peritoneal fluid of both showed the presence of leptospiræ and they died on the 8th day after their birth. The second guinea-pig showed no evidence of infection and delivered 3 healthy young ones a week after the inoculation. The mother and offspring remained alive and well for more than 4 weeks, far beyond the usual fatal period. Guinea-pigs nos. 3 and 4 delivered dead immature young ones on the 5th and 6th days, respectively, after inoculation. The histopathological examination of the foetal tissues (liver and kidneys) was negative, but the guinea-pig inoculated with the liver emulsion of one of the young ones of no. 3 animal died of leptospiral jaundice, the organisms being present in large numbers in the liver and kidneys.

The remaining 3 expectant mothers were sacrificed when leptospiræ were detected in their blood. In one, although the presence of the organisms could not be demonstrated in the foetuses by direct microscopical examination of the liver and kidney emulsion or by the examination of the sections of these organs, yet inoculation of the liver emulsions produced fatal leptospiral infection in the guinea-pig, as in the case of the guinea-pig no. 3. In order to be sure that these foetuses were not infected with the mother's blood during their removal from the uterus the following measures were adopted:—

On opening the amniotic sac of guinea-pig no. 5 the foetus was carefully removed, the cord was ligatured and the foetus was immersed in a bowl of lysol lotion (1:100) for 5 minutes so that contamination with the mother's blood, if

(Continued at foot of next column)

A NEW METHOD FOR THE DETERMINATION OF SMALL QUANTITIES OF COCAINE IN PRESENCE OF NOVOCAINE

By RAI BAHADUR K. N. BAGCHI

H. D. GANGULI

P. N. MUKERJEE

and

J. N. BANERJEE

(Department of Chemical Examiner to the Government of Bengal, Calcutta)

THE smuggling of cocaine is carried on on a large scale in spite of the vigilance of the excise department and frequent convictions of the smugglers. The cocaine addict, however, very seldom gets a pure salt of cocaine from the smuggler who invariably adds to it all sorts of adulterants, viz, boric acid, earbonate and bicarbonate of soda, lime, chalk, aspirin, anti-febrin, and starch. Lately, novocaine has been introduced in the field and has become very popular with smugglers on account of its deceptive appearance and somewhat similar, although transient, physiological effect on the tongue. The samples of cocaine seized by the excise and police officers and sent to this department for analysis are found to contain a very high percentage of novocaine and in some samples no

(Continued from previous column)

any, could be eliminated. The foetus was next washed in several changes of sterile saline. The liver and kidneys were removed and the emulsions of these organs were examined under the dark-ground illumination with negative results, but a young guinea-pig inoculated with 1.5 c.cm. of this emulsion died of leptospirosis 8 days later.

Of the two remaining pregnant animals, especially the one which showed a fairly heavy infection of the blood, the presence of leptospiræ was demonstrated in the sections of the foetal liver.

Conclusion

Young guinea-pigs born 30 hours after the infective inoculation of the mother showed no evidence of infection at birth. The infection at a later period was apparently acquired by association with the infected mother. Definite evidence of the transmission of leptospiræ from the mother to the embryonic guinea-pig has been obtained, and is shown by the presence of the organism in the sections of the foetal liver; the work of Saenz is thus supported.

cocaine at all is detected. As novocaine does not find a place in the schedule under the Dangerous Drugs Act promulgated by the Government of India in 1930, its import, sale and use as an adulterant of cocaine are not restricted. Addicts are unable to detect the fraud and mistake it for cocaine. The small powders containing about 3 grains of a white stuff, supposed to be cocaine hydrochloride and put on sale by the underlings of the smugglers, sometimes contain only novocaine although the fabulously high price of cocaine is charged all the same. Addicts, or cocaine eaters as they are called, often spend a considerable amount to obtain an adequate dose of cocaine for producing the desired effect but in fact they take novocaine mixed with a trace of cocaine, or only novocaine which never produces the same feeling of exhilaration and 'sense of happiness and well-being which transport at once to a longed-for elysium', Brundage (Lyon, 1935), as they expect from cocaine hydrochloride. In this way they go on consuming a large quantity of novocaine, sometimes with a fatal result. In the annual report of this department (Bagchi, 1938) the case of an addict who spent seventy rupees (about five guineas) in one evening to get the full dose of cocaine and then died of novocaine poisoning in about five hours was reported last year. Perhaps many more cases of this nature suffer the same fate but are never brought to light.

In trying these cases of illicit sale of cocaine, the magistrates want to know the amount of cocaine salt actually present in an adulterated sample. The determination of a small quantity of cocaine in the presence of novocaine is difficult and no satisfactory method of analysis is available in the literature. Several methods of detection of cocaine in the presence of novocaine have been described by Young (1931), Wagenaar (1932), Sanchez (1934) and others, but none of those methods could be suitably modified for quantitative determination of cocaine according to our requirements. Riley's method (1935) is too cumbersome and Nicholls' method (1936) does not work well with much excess of novocaine. A new method was worked out in this department and was given a fair trial for a sufficiently long time with satisfactory results, and we believe that it is at present the best method for the determination of a cocaine salt in the presence of even a large excess of novocaine. The method works equally well in the presence of other adulterants stated above and is based on the facts that gold chloride gives a crystalline precipitate with both cocaine and novocaine and that the novocaine gold chloride compound is soluble in dilute hydrochloric acid while the cocaine gold chloride compound is insoluble in the same acid.

Method of carrying out the determination

Preliminary test.—A preliminary examination as to the actual constituents of the powder is desirable. The characteristic fern-like crystals (Stephenson, 1921) produced by gold chloride

will indicate the presence of cocaine. The crystals are obtained even in dilution of 1 : 20,000 (Allen, 1929). The number of crystals found in three or four consecutive fields of the microscope is likely to give an idea about the amount of cocaine present in the mixture. The presence of alkaline carbonate and other adulterants is also to be tested by the usual method.

Actual experiment.—About 0.5 gramme of the sample accurately weighed is dissolved in about 20 ml. of dilute (10 per cent) hydrochloric acid (B. P.) in a small beaker. About 2.5 ml. of one per cent gold chloride solution are added drop by drop to the acid mixture until the precipitation of cocaine gold chloride is complete. During addition of gold chloride solution the mixture is stirred and the sides of the beaker are scratched with a glass rod for rapid precipitation. The yellow precipitate of cocaine gold chloride is at first amorphous but soon becomes crystalline and begins to settle. In about two hours it settles completely and is then filtered through a small filter (Swedish paper no. 00). The residue is carefully washed with about 15 ml. of cold water (5 portions of three ml. each) till the filtrate is free from novocaine as indicated by a drop of paradimethyl-amino-benzaldehyde solution (one gramme in 95 ml. of absolute alcohol and 20 ml. of concentrated hydrochloric acid) which gives a yellow coloration with novocaine (Chakravarti and Roy, 1937). The residue is then washed with 20 ml. of water into a separating funnel of about 50 ml. capacity by perforating the filter. The mixture is rendered strongly alkaline with 10 per cent solution of ammonia which decomposes the double salt and liberates the cocaine base. The free alkaloid is then extracted with peroxide-free ether (anaesthetic ether B. P.) using 25, 20, 15, 10 and 5 ml. portions. After the final extraction the solution is tested with a drop of Meyer's reagent to see if the alkaloid has been completely extracted. The first two ether extracts are washed with 5 ml. of distilled water and transferred to a tared platinum crucible. Each of the remaining three ether extracts is also washed with the same wash water and is combined with the first two portions in the platinum crucible. Finally, the separator is washed with a few ml. of ether which is then shaken with the wash water for extraction of the last trace of the alkaloid. The greater part of the combined portions of ether is evaporated on a steam-bath and the remainder is evaporated spontaneously at room temperature. The platinum crucible is then transferred to an air oven and dried at about 70°C. to a constant weight. The weight of the alkaloid (cocaine base) multiplied by the factor 1.12 gives the amount of cocaine hydrochloride actually present in the sample.

For confirmation of the above result the dry alkaloid in the platinum crucible is dissolved in a few ml. of neutral alcohol and then 20 ml. of 0.02 N H_2SO_4 are added and the solution is titrated with 0.02 N NaOH using methyl red as

an indicator. One ml. of 0.02 N H_2SO_4 consumed is equivalent to 0.00679 gramme of cocaine hydrochloride.

Precautions

(1) The amount of gold chloride solution usually required for complete precipitation is about 2.5 ml., but the actual amount depends upon the quantity of cocaine present in the mixture. If it is present in excess and novocaine in small quantity, more gold chloride (3 ml. or even more) will be required. It should always be present in slight excess to ensure complete precipitation.

(2) The amount of acid to be added depends upon novocaine present in the sample. If there is less acid there will be a brown coloration due to the reduction of auric chloride. A slight excess of acid is therefore necessary to prevent the reduction of gold chloride and also to keep novocaine in solution. It is desirable not to increase the bulk of the mixture. Ten ml. of 20 per cent acid is preferable to 20 ml. of 10 per cent acid.

(3) For washing the residue in the filter, smallest quantity of water is to be used, as cocaine gold chloride is slightly soluble in water.

(4) The presence of chalk, antifebrin, aspirin, starch, etc., along with novocaine does not interfere with the determination. They are easily removed from the solution by a preliminary filtration, but the presence of alkaline carbonates and lime necessitates the use of stronger (20 per cent) hydrochloric acid. In other cases 10 per cent acid is quite good.

(5) As gold chloride is soluble in ether it is desirable to perform a blank experiment with all the reagents as employed in the different stages of the method and the figure obtained by this way should be deducted from the final weight of the alkaloid.

(6) A tall platinum crucible or a small pyrex beaker should always be used for evaporation to prevent loss by creeping during evaporation.

FURTHER OBSERVATIONS ON LEPTOSPIRAL INFECTIONS IN CALCUTTA

By B. M. DAS GUPTA

(From the Department of Protozoology, Calcutta School of Tropical Medicine)

It has been shown in a previous communication (Das Gupta, 1938) that the cases of leptospiral jaundice described in Calcutta were all infected with the organism of the same serological type, being identical with a classical Dutch strain.

Since then more cases have cropped up, one of which is quite important in that the infecting organism belonged to a different serological group and the laboratory confirmation would not have been possible had not the serum been tested with several strains isolated in other parts of the world. A note on this case is published so that it may serve as an object-lesson to other workers engaged in the study of this disease.

The patient showed nearly all the important clinical signs of typical Weil's disease, such as hæmorrhages, intense jaundice and signs of renal irritation, and died within a few hours of admission. He was seen on the sixteenth day of illness, i.e., at the time when the infective period of the blood was over. Blood was, therefore, taken for serological tests alone. As the serum did not give any significant reaction with the local strain, nor did it protect young guinea-pigs against the same strain, a little of it was sent to the Schüffner laboratory at Amsterdam with the request that the test might be performed with all the strains in its possession. The results of

Indian Medical Gazette

JANUARY

MEDICAL EDUCATION AND RURAL MEDICAL RELIEF

At the end of last year the Director-General, Indian Medical Service, published a general review of the medical services in India*. It is surprising that this has never been done before and, now that we have this volume beside us, we begin to wonder how we managed to get on without it, for it contains a ready answer to so many questions that in the past would have necessitated searching through numerous provincial reports and to others that could only have been answered by personal enquiry.

To people in India interested in medical education, medical relief, or preventive medicine (who amongst the intelligentsia of the country are not, or should not be?) this volume will be invaluable, but to those in foreign countries who are similarly interested, perhaps for no better reason than to make a comparative study with the medical problems in their own, it will be a revelation; they cannot fail to be impressed with the immensity of the problems, the multiplicity of the means by which they are being met, and, alas, the huge gaps that still exist in the medical organization of this country.

The *Review* is a dispassionate statement of facts: it is neither a eulogium of the various governments' efforts, nor propaganda by the medical department for the consumption and encouragement of legislators. Critical comparisons between the states of affairs in different provinces are avoided, but it will be a good thing for each province to be able to see where it fails in comparison to other provinces, as it would have been to see where they all fall short, had comparative figures been given from some advanced western countries.

The limiting factor is of course in nearly every case finance. It would be absurd to suggest that the medical organization of this country was perfect and that the best possible use was being made of the money available, just as it would be to suggest that no more money could be spared for the medical services by the central and provincial governments. But, on the other hand, there is no obvious waste of the funds allotted, nor do the contributions from governments compare, on the basis of the percentage of total resources, at all badly with those made by other governments to the medical services of

their own countries. It is probably in the inadequacy of the provision made for medical relief by local bodies, in the rarity of bequests by wealthy philanthropists, and in the poorness of the charitable contributions by the people themselves that India falls so far short of western countries.

Perhaps the most interesting chapters in this review are those on medical education and rural medical relief, subjects which are intimately connected. The state of education in the medical colleges in India must on the whole be considered satisfactory; the preliminary education required to qualify for admission is high enough to ensure that the majority of the candidates are of the right standard, and the length of the course and the facilities for teaching are such as to allow the outturn of graduates with a medical education that compares well with those of the universities of other countries. There is one aspect of the medical college question that attracts our attention, and that is, provincial bars to the entrance of students. The state of affairs has been unsatisfactory in the past and with the establishment of the new provinces it will become worse. It is very natural that a native of one of the smaller provinces should feel acutely disappointed when he finds that he can only become a medical graduate by paying an exorbitant fee to gain entrance to a foreign (provincially speaking) medical college, and then only if he is very lucky. Such a disability will naturally lead to a demand for a medical college in each province. To attempt to meet such a demand in some provinces is out of the question and in others would be most unfortunate; the time for multiplying medical colleges in this way has not come. At present there are nine medical colleges distributed between six provinces, excluding the medical college for women at Delhi, which is mainly supported by the Government of India, so that in nine provinces, including the Central Provinces, Assam, Sind, Orissa and the North-West Frontier Province, there is no medical college.

It is suggested that the question of establishing a medical college on an all-India basis at Delhi or elsewhere should now be considered. The present inequality could, however, be rectified immediately by the richer provinces opening their doors a little more widely to 'foreign' students from the poorer provinces, only we are afraid that the spirit of provincialism too often outweighs that of nationalism, and that inter-provincial generosity of this kind is too rare for us to entertain any great hopes of an easier solution of the problem on these obvious lines.

If the state of medical education at the medical colleges can be considered satisfactory, that at the medical schools in India cannot. A previous Director-General laid down a standard for medical schools, based on the number of patients available for teaching and on the equipment of the institution. The standard cannot be

* *An Indian Medical Review*. By Major-General E. W. C. Bradfield, C.I.E., O.B.E., K.H.S., I.M.S., Director-General, I. M. S., 1938. Published by the Manager of Publications, Delhi. Pp. 658.

considered a high one, yet of the 27 medical schools in India, only one conforms to this standard, eight are deficient in two out of three points and eighteen are deficient in all three points.

Among the licentiate class of practitioner there are many men who in knowledge and efficiency are far above the average of the graduate practitioner and there are probably some graduates who would compare badly with the average licentiate, but it stands to reason that the ill-equipped and over-crowded medical schools in India must lead to the turning out of many men with a standard of medical education far below what ought to be considered the minimum standard for doctors qualified to practise scientific medicine. Judged from any point of view the production of a class of sub-standard medical men must be considered most unsatisfactory.

How can it be remedied?

There are two courses open, one to raise the standard of these schools, the other to close them down. In many instances it should undoubtedly be possible to raise the school to the requisite standard, but this would probably mean a stricter limitation of entrants. In any case any widespread reform in the medical schools will mean a much smaller output of qualified medical men.

Will this be a satisfactory result?

There is already considerable unemployment amongst medical men and this measure might assist in reducing the ranks of the unemployed, but on the other hand the rural areas want medical relief and the better their education the less willing will medical men be to bury themselves in the country, so that again we come to an impasse.

Whatever is to be the solution of rural medical relief it does not seem to us that the production of a large body of substandard medical men will provide the answer. There should be one standard only for medical qualification in this country; this ideal cannot be achieved by a stroke of the pen and the admission of medical men of all standards to one register, but will only be attained by raising the standard of education of the licentiates to the level of that of the graduates.

The number of the population served by each hospital or dispensary varies in the different provinces from 11,305 (Baluchistan) to 81,087 (United Provinces) and in the large provinces the average is about 50,000. The average area served varies from 24 square miles (Delhi) to 1,327 square miles (Baluchistan) and the average in the larger provinces is probably in the region of 250, though in Bengal it is 540 square miles. If the larger towns, where each hospital serves a much smaller area, are excluded the average area served by each of the remaining hospitals or dispensaries will be greater.

In most rural dispensaries there is one medical officer who has to serve an area with a radius of 10 miles approximately and a population of 50,000 persons. The monthly expenditure in rural dispensaries varies considerably but on the average it is certainly less than Rs. 200 in most provinces; this after the deduction of salaries leaves remarkably little for drugs and equipment.

There is again in the different provinces a considerable variation in the *per-capita* cost of medical relief. In 1936 it varied from Re. 1-2-5 in Delhi to one anna in the United Provinces, in Bengal it was Re. 0-2-1, and in the Punjab Re. 0-5-7, the highest figure in the larger provinces. Whatever schemes for rural medical relief are adopted, it is quite certain that no satisfactory solution will be found in some provinces unless more money can be devoted to this purpose.

Money, however, is not the only difficulty and even with a generous dispensary and travelling allowance a doctor would find it difficult to serve so large an area without assistance of some kind. The establishment of subsidiary 'consulting rooms' in a number of villages which he could visit in rotation has been suggested, but these would be of little use unless they had dispensaries (in the stricter sense) where at least stocks of the more commonly used drugs could be kept.

The question of unqualified assistance, that is the employment of some educated person in the village (e.g., the schoolmaster) to give 'first aid', then comes up. The objection raised against this is that in time such a person 'is too inclined to set himself up as a fully-qualified doctor to the general disadvantage of the village'. We do not like this argument. It is suggestive of petty resentment at any possible encroachment on our professional reserves, and the jealous guarding of trade secrets. An unqualified person given an official position in a village should of course be strictly limited in his activities and any attempt on his part to assume the title of doctor should lead to the cancellation of his official status, but there is nothing to prevent anybody practising the healing art, as long as they limit their dispensings to medicines whose actions they understand and to simple empiricisms, and their surgical practice to the antiseptic dressing of wounds and possibly the opening of superficial abscesses. Were a qualified doctor placed in a similar position with the same limited scope, medicines and equipment, he would probably very soon sink to the level of the first-aid-trained schoolmaster. The more serious aspect of this is that he would then lower the status of the qualified practitioner of scientific medicine in the eyes of the people; they would see no difference between the qualified and unqualified dispenser of medicines. The village practitioner of indigenous medicine, if he were the genuine article and not an opportunist without traditional training, might be better than either of them, as he has been

trained to make use of local resources, when dispensary stocks are low, which they almost invariably are.

At the present time the villager with fever may have to walk 10 miles to get his dose of quinine, or, even if the system of touring the villages were introduced, to wait a week or more. Wouldn't it be better to have some responsible person locally who could give him cinchona mixture on the assumption that it was malaria and later if necessary advise him to see the doctor when he visits the locality, even at the risk of this person occasionally usurping the position of the doctor? The unqualified assistant

would be placed under the orders of the doctor, who, with his far more extensive medical training and wider scope in his position as doctor in charge of a comparatively large area, should have no difficulty in maintaining his status in the eyes of the villagers.

Everything should be done to increase the margin between the qualified and unqualified practitioner, but only by raising the status of the former, so that in time the people are led to appreciate the advantages of scientific medicine, when they will themselves demand, and find the money to support, a far larger body of rural practitioners.

NUTRITIVE VALUE OF RICE

By A. SREENIVASAN, M.A., D.Sc., A.I.C.
(Indian Institute of Science, Bangalore)

RICE is the staple cereal food of more than half the world and of the vast majority of the population in India and in the East in general. There are several hundreds of varieties already in existence; dozens of new ones are being added each year by the breeder. Improvements in rice culture have been hitherto only along the lines of increasing yield and other qualities that enable the cultivation of a successful crop. Very little attention has been directed towards evolving nutritively superior varieties.

In spite of the bewildering number of rice varieties, the consumer is not often at a loss in choosing his desired quality. It is not always, however, that his choice is also the best from the nutritive point of view. The consumer bases his preference only upon popular impressions gained from general experience. There is no foundation for the frequently expressed opinion that rice, in spite of its extensive use, is a poor article of food, for it is possible, under certain conditions, to enhance greatly the food value of rice as ordinarily consumed.

Chemical composition of rice varieties

The chemical composition of rice has been determined by a number of workers (*vide* Sadasivan and Sreenivasan, 1938) and it has been stated that the average values for the different constituents, such as the proteins, fats, carbohydrates and mineral matter, fall within a fairly close range. However, recent work in the writer's laboratory has shown that the composition is more variable between varieties than has hitherto been supposed. Thus, proteins vary from 7 to 11 per cent, phosphoric acid from 0.6 to 1.2 per cent and lime from 0.06 to 0.11 per cent. Of especial significance has been the observation that coloured and coarse-grained rices generally contain larger amounts of proteins and minerals, particularly phosphorus,

calcium and iron, than the so-called 'superior' fine varieties, which are most favoured by consumers. The coarse varieties have to be polished to a higher degree than the fine ones before a white grain results; they also do not usually possess good milling qualities (Sreenivasan *et al.*, 1938); hence, it follows that under ordinary conditions of milling, the extent of loss of essential constituents from such rices is less than from the fine white rices. That coloured and coarse varieties contain thicker bran layers has also been shown from histological examination of rice varieties (Ramiah, 1936). It has been stated (Kennedy, 1924) that wild rice has a greater food value than cultivated (fine) rice, the proteins being of better quality and the content of vitamin B₁ greater.

Effect of manuring and duration of crop on composition

Improvements in the quality of rice by increasing the protein and mineral contents of the grain can be effected by judicious control of fertilizer applications. In particular, application of fertilizers in instalments during the life of the crop and up to the flowering period is definitely favourable, the protein content being increased in one instance to the extent of 20 per cent. In field behaviour, it has been experienced that the yield is also improved by such applications (Paddy Specialist, Madras, *private communication*).

It is generally believed that short-duration varieties of rice are poorer in quality than the long-duration ones. Thus, in Madras the *kar* varieties are not valued so much for their nutritive value as the *samba* ones. Similarly, in Bengal, *aus* rice is held inferior to the *aman* rice (Acton and Chopra, 1925). Recent researches by the author show that there are many short-duration rices which are richer in composition than the long-duration ones. The results of experiments on the quality of the proteins of pure strains of *aus* and *aman* rice (Basu and co-workers, 1935, 1937) have revealed that the

latter are probably better. More extended experiments are needed to show whether there is any scientific basis for the popular belief in regard to short- and long-duration varieties.

Dry and wet cultivated rices

Rice is essentially a wet crop but there are some dry varieties grown in certain parts of the country and are valued as such. Sir R. McCarrison (1928) showed that they are more nutritious than the wet cultivated rices. More recent work by the writer does not entirely support this view. When the same variety is grown under dry as well as wet conditions, the latter contains greater percentages of protein and mineral matter and promotes better growth in animals. The development of the bran layers is also more in this case (Paddy Specialist, Madras, *private communication*). Irrigated rice is also the more productive, yielding nearly three times as much as the dry crop.

Growth experiments with rice varieties

Extensive feeding experiments on young albino rats and pigeons have been carried out with the different varieties of rice. The differences in growth rate obtained with the varieties are essentially related to their composition. The weekly average increases in weight for the different groups range approximately between 4 and 6 to 7 grammes with the different varieties. There is no doubt that, other things being equal, the variety of rice which contains the greater amounts of albuminoids and minerals, such as phosphorus, calcium and iron, is the more valuable. The present popular favour is, however, as already observed, for the fine-grained varieties which are deficient in nutritional factors. The reason for this anomaly is not far to seek. The plant breeder has only been catering to the popular demand for the fine and high-yielding varieties. Nutritive value has yet no place in his scheme. The result is that he has gone on selecting varieties which are mainly starchy and poor in other ingredients. If, on the other hand, the public awaken to the situation and demand nutritively superior varieties, the position will no doubt soon be reversed.

The proteins of rice

The average protein content of rice is rather small compared to that of other cereals. Still, rice protein is highly nutritious and contains all the essential amino-acids (Hamada, 1923). In its general amino make-up, it has been compared to the majority of the proteins of meat, milk and soya beans (Mitchell and Villegas, 1923). Rice protein has a high biological value (86), higher than that of wheat (67) (Mitchell, 1924, Mitchell and Carman, 1924). For the maintenance of nitrogen equilibrium, rice protein is superior to wheat protein and appears to be as efficient as animal proteins (Basu and Basak, *loc. cit.*). These should justify the extensive use of rice as an almost exclusive article of diet in spite of its

somewhat low protein content. Recent work at Bangalore has shown that the biological value of the proteins of rice in a mixed diet is greatly increased by the addition of supplements of calcium (Ranganathan and Rau, 1938). Addition of skimmed milk or calcium lactate has also been shown to enhance greatly the nutritive value of a rice diet (Wilson, *et al.*, 1936; Aykroyd and Krishnan, 1937).

Calcium and phosphorus in rice

Rice is notoriously deficient in calcium but it is a very good source of phosphorus. The phosphorus occurs mostly as phytin in organic combination (Rather, 1918) and in this form is not easily assimilable by the animal organism (McCance and Widdowson, 1935; Lowe and Steenbock, 1936). This point is of some significance in connection with the production of rickets resulting from excessive cereal consumption (E. Mellanby, 1925; M. Mellanby, 1929; Bruce and Callow, 1934). The availability of phosphorus in rice can however be increased in a number of ways. The ratio of calcium to phosphorus in a diet is an important factor affecting their availability in nutrition. In rice, this ratio is approximately 1:10, a proportion not well suited to the needs of the animal body which are better met by a calcium-phosphorus ratio of 1:1 or 2 (Sherman, 1937). Hence, supplements of calcium in the form of milk, vegetables and other food articles will favourably influence the assimilation of the phosphorus compounds of rice. Vegetables in particular contain more calcium than phosphorus (Ranganathan *et al.*, 1937) and have therefore an unbalanced mineral ratio just opposite of that in rice. The addition of vegetables to a ration containing rice would naturally balance the mineral ratio. Vegetables are also a good source of *phytase* which hydrolyses and renders available the phytin of rice. Rice itself contains this enzyme in a small concentration (Giri and Sreenivasan, 1938) and it is possible, under suitable culinary conditions, to increase greatly the availability of the phosphorus and other minerals in rice. The possible presence of a *phytase* in the intestines of human and animal organisms has been the subject of numerous recent inquiries (*cf.* Patwardhan, 1937), but the evidence is yet largely inconclusive.

Superior nutritive value of parboiled rice

During recent years, a considerable amount of attention has been drawn to the high antineuritic and nutritive value of parboiled rice even after some polishing (Braddon, 1911; Fraser and Stanton, 1910, 1911, 1914; McCarrison and Norris, 1924; and others). The scientific basis for this remained rather obscure until it was shown by Aykroyd (1932) that during the process of parboiling, the endosperm absorbs vitamin B₁ at the expense of the germ and pericarp and that polishing does not therefore remove the vitamin to the same extent as with

the untreated rice. More recent work by the writer has shown that there is a similar absorption of the proteins and minerals as well from the integuments by the endosperm (Sreenivasan *et al.*, 1938). Furthermore, parboiled rice of commerce is often prepared only out of the coarse (rich) varieties of rice which do not mill well when raw. Another point of interest in this connection is that, being less easy to polish than raw rice, parboiled rice is generally undermilled.

Commercial parboiled rice has often a flavour to which some object and also an unattractive appearance. These are due to bad water being used over and over again during the preliminary process of steeping (Charlton, 1923) and can certainly be improved; indeed, ideally prepared parboiled rice has a very pleasing flavour and nearly white appearance. The superior nutritive value of parboiled rice together with its other desirable qualities (Sreenivasan and Das Gupta, 1936) should make the production and use of this article more extensive than hitherto.

The polishing of rice

Until a few decades ago, rice was almost entirely hand-pounded. The resulting grain was necessarily somewhat dull-coloured. With the march of progress from primitive to modern conditions and with the introduction of cheap and more efficient machine-milling, there has been a rapid disappearance of the traditional methods of stone-grinding and hand-hulling with the result that to-day unpolished rice is a rare article for which a special price has to be paid.

In considering the nutritive value of rice, the feature of outstanding importance is the high concentration of essential nutritional factors in the peripheral layers of the grain. The outer envelope or bran and the germ together constitute over a sixth of the whole grain, the remainder being the endosperm of polished rice. They contain more than half to three-fourths of the mineral matter of the grain, over 25 per cent of the protein and practically all the vitamins and fat (Sreenivasan *et al.*, *loc. cit.*). These are the very portions that are lost during milling. In spite of this recognized loss which the grain suffers during polishing, there has been a general and widespread preference for the milled rice. Why is this? The reasons are that polished rice has a pleasing appearance and texture, it cooks more easily than the unpolished grain and digests better and, in the raw condition, it has far better keeping qualities and can be stored easily for long periods without any appreciable deterioration.

Keeping quality of shelled rice

Shelled, unpolished rice undergoes rapid and almost day to day deterioration. The outer coats of the grain contain an enzyme capable of splitting the rice oil. Under the action of moisture and this *lipase*, the bran is easily decomposed, resulting in the production of free fatty acids and other rancidity changes. Polishing

results in the removal of a major part of the rice fat and of the fat-splitting ferment. Hence polished rice has a much better keeping quality. This quality is the one which appeals to the largest section of both producers and consumers. It is in fact the chief reason that militates against the introduction of any major legislation to check the wholesale replacement of unmilled rice by the milled product.

Desiccation combined with air-tight packing or storage in presence of carbon dioxide gas can be successfully employed for the preservation of unpolished rice but concerted search for other cheap and efficacious methods should be made.

Digestibility of unpolished rice

There is a general impression that unpolished rice is more difficult to digest than the polished rice. While it is true that the bran constituents are comparatively more difficult of digestion, yet the difference in digestibility between unpolished and polished rice is too small to be of any significance in practice (Sreenivasan and Giri, not published). Unmilled rice is richer than the milled rice and should therefore be eaten in smaller quantities.

Mode of preparation of rice

Repeated attention has been drawn to the wasteful processes of washing rice before cooking and of throwing away the water in which the rice is boiled during cooking (McCarrison and Norris, *loc. cit.*; van Veen, 1933, 1934; Rudra and Bagchi, 1933; and others). Happily, there has been some improvement in regard to the latter, for, in most well-regulated households, only enough water is used to enable the rice to cook to its proper consistency; where a certain excess of water is used, this is frequently fed to cattle and not thrown away. The losses on washing which are even more wasteful (Sreenivasan, *et al.*, *loc. cit.*) are less well recognized. Washing is perhaps necessitated on account of certain extraneous articles being used as glazing materials to rice. It should be possible to prohibit by proper legislation the use of non-food articles for coating bazar rice so that rice can be cleaned before cooking by some process of dry cleaning.

Need for changed outlook and propaganda

It has been stated often that wheat is more 'health-sustaining' than rice. If the comparisons be made on the basis of identical dietary proportions of the whole grains of either wheat or rice, no evidence can be adduced to justify our placing the one in a higher nutritional category than the other. It is true that wheat is generally richer in regard to proteins, but rice protein is much more nutritious. Besides, there are certain varieties of rice which compare favourably with wheat in this respect. Further search will perhaps reveal varieties which are nearly as rich as wheat in composition. It is also possible to enhance the nutritive value of rice by suitable

systems of manuring and by alterations in food habits. The poor quality of the food as ordinarily eaten is traceable to the choice of wrong varieties and refined conditions such as polishing, washing and cooking involving considerable losses of nutritive elements. The one feature which distinguishes rice from wheat, and indeed from all other cereals, is that it is primarily consumed in the milled state. It is absolutely essential to do away with this very wasteful process. The League of Nations Inter-governmental Conference on Rural Hygiene has emphasised that *the problem of nutrition throughout the East is intimately connected with the degree of milling to which rice is subjected before being consumed.*

As with other cereals, the nutritive importance of rice lies primarily in its fuel value. It has a high *calorific value*, higher than that of wheat although, as observed by Wilson (1937), rice, when ready for consumption, is bulkier and contains more water than a quantity of wheat of equal calorific value; the higher water content of the former may be advantageous in a tropical climate, there being an increased reservoir of water for evaporation and urine secretion, thus regulating body temperature.

Rice, however, is imperfect in itself as a food and should form part of a good *mixed diet*. Not only should the necessary supplements be found and taken (c.f. Surie, 1936), but they should also be intelligently incorporated in the food. Present-day rice diets are highly monotonous, practically every course consisting of rice with but little variety or supplements. In addition to finding cheap components that will make the average rice diet a complete food, new methods of cooking them should also be introduced.

There is great need for research in the direction of evolving, by suitable selection and breeding work, nutritively superior varieties of rice and of preserving without deterioration, rice with its nutritionally rich bran layers. The public should also be educated in regard to the use of whole, unmilled rice, especially coloured or coarse varieties known to be rich in essential constituents. Increased use of such rice will greatly improve the present status of the rice diet and will result in better growth and greater improvement in the general health and well-being of a very large section of the population of India.

A MEDICAL TOUR IN RUSSIA

By MAJOR-GENERAL SIR CUTHBERT SPRAWSON

Kl., C.I.E., M.D., F.R.C.P.

Late Director-General, Indian Medical Services

I

RUSSIA is a country that has certain analogies with India. Both are countries with populations mainly agricultural, but becoming somewhat industrialized and urbanized. This process is much more advanced and more rapid in Russia than in India. It has occurred to me after recently making a medical tour in European Russia that a brief account of the ways in which the Soviet is tackling some problems similar to those which India has to face might be of interest to readers of the *Indian Medical Gazette*.

There are of course many basic differences between the two countries as well as between their Governments. The first thing that strikes one on entering Russia is that it is a country of the young: no one about the streets seems to be over 35 years of age. One sees a few elderly women, but I saw hardly any old men except in hospital wards and in rural areas. When I asked for figures on this point, I was told that 46 per cent of the population were born since 1917 and that only 6 per cent were 60 years and over. The Soviet Union has now a population of 170 millions, increasing annually by 3 millions. One basic difference from India should be realized, that is that practically everybody, men and women, go out to work. The children from the age of two months to 18 years are for the most part lodged out for the day in a nursery or school, returning usually to the home in the evening. This arrangement appears to be completely carried out in towns, less so in the country.

One cannot see everything in a three-weeks' tour, however well that may be arranged, and the tour and travelling were both well organized; but I had told the Soviet authorities previously that my chief interests were in leprosy, tuberculosis and medical education and though I concentrated principally on those subjects I saw something of public health and of other activities as well. In leprosy I do not think they had anything to teach us, so I omit that subject now and will give a short account only of their medical education and of their campaign against tuberculosis.

Medical education

Russia is the only country other than India I know that still has a dual standard of medical education. There are the University graduates who after ten years at school undergo a five-years' medical course: and there are the *feldshers* who have only seven years at school followed by a three-years' medical training. Moreover the origin of the *feldsher* is similar to that of the sub-assistant surgeon and arose in military

requirements. Originally all European armies had field surgeons who were not graduates, in addition to some of the graduate class. It is now many years since the other nations abolished this class and had only graduates or diplomates of a high standard; but Russia, not being able to train enough graduates, retained the *feldsher* and he practised also in civil life. When the Soviet Government took charge they considered abolishing the *feldsher* class, but found it impossible for the present owing to the shortage of doctors; so the system continues and the total number of *feldshers* is now larger than ever before. Before the Great War the number of *feldshers* was larger than that of the graduates in the proportion of 3 to 2: and although the number of *feldshers* has increased the number of graduates has increased much more in proportion.

At the present time the number of medical students, graduates and *feldshers* is huge: there are about 96,000 undergraduates and about 45,000 *feldsher* students. Possibly when they have got their numbers up to their requirements the Government will again consider abolition of the *feldshers*.

Before the war there were in Russia between 20,000 and 25,000 graduate doctors. Doubtless several hundreds fell in the Great War, but after that war the casualties were much higher, both in the civil war and in the typhus epidemics, which were particularly fatal to doctors. As soon as the funds of the Soviet Government allowed, great efforts were made to replace the loss, and increasing numbers of medical students were taken annually. This explains the very large numbers given above. It should be understood that more than half of these students are women. In the Leningrad First Medical Institute, which I saw, about 75 per cent of the students were women. At this institute there were about 3,000 students, including a recent admission of 900 fresh students. As the First Medical Institute is only one of those in Leningrad, which city has a total of 10,000 University medical students, I was interested to see how they could deal with such enormous numbers. I suspected the medical schools and hospitals must be overcrowded and in my opinion they are overcrowded to an extent that must cause the instruction given and the standard of qualification to suffer. The First Institute had a hospital of 1,200 beds: the beds were closer together than we should allow. I was told that in addition the students had access to about another 1,000 beds in other parts of the city; but even these combined numbers must leave the clinical material insufficient. The laboratory work must be most difficult to arrange. The 900 students work in four batches, and both lectures and practical work are repeated to each batch. There is one microscope per student on each shift, so that the same microscope is in the care of four separate students at one time through

the term. In other countries the number of midwifery cases would be a difficulty, but in the Soviet every woman goes to hospital for childbirth and may be used for teaching purposes, so that each student manages to see ten cases of delivery before qualification.

From what I saw of both medical schools and hospitals they appear well equipped with necessary apparatus.

In the U. S. S. R. there are 72 institutes educating these undergraduates. This includes not only medical colleges such as the Leningrad Institute mentioned above, but also institutes of hygiene of which I saw an excellent specimen in Moscow. The system is peculiar in that it allows specialization in public health during the course so that a student can qualify in five years with his diploma in public health as well. Thus a student entering the Moscow Institute of Hygiene can select either general medicine, public health or pediatry as his line of study. For the first three years the course is the same for all. After that time if the student elects for general medicine or pediatrics he is probably transferred to the Second Moscow Medical Institute, though he may, if he prefers, stay on at the Hygiene Institute. They all receive qualifications entitling them to practise medicine, and even the hygienists receive instruction, though less than the others, in clinical medicine: but the last two years of the course has a bias towards the speciality the student has selected.

In the whole U. S. S. R. 25,000 new students entered in 1938. Of this number 4,000 selected pediatry and 3,200 public health, leaving the balance for general medicine. This early specialization is by way of an experiment and the Soviet authorities are watching the results: it has been going on since 1934.

Apart from the continuance of the *feldsher* class, whose education I did not study, it would seem that the graduate class must now be receiving an education that we should consider somewhat inferior. The Soviet authorities doubtless recognize this, but are concerned first to get their numbers up and to improve the quality later. If there were 25,000 doctors in 1914, there are 107,000 now, which allows one doctor for 1,588 of the population. The Soviet aim at having one doctor per 1,000 of population: hence the efforts at increase.

Now to compare the position with that of India which has a still greater population and still fewer recognized doctors. And yet doctors in India, even of good quality, often have a difficulty in making a living. There are basic differences in the conditions of employment in the two countries. In the Soviet all doctors are State employed: there is practically no private practice. At first the young graduates have to go where they are sent. Paradoxically the best students are sent to the most remote and less desirable places, because in such places and in primitive conditions they would have to rely more on themselves and

the students who get the highest marks are considered most capable of doing this. In the less desirable places they are paid more and may get such special privileges as a motor car or a cow and longer holidays. If married, his wife will also have to work and may be sent somewhere else. It was explained to me that after one or three years they could go where they liked and practise, a minimum of five hours' work a day being demanded: but I could not understand how it was possible to administer a State medical service if everyone went where he liked. There seems no desire to flock to the towns as in India: a public and pioneer spirit was said to lead the young men to rural districts. During undergraduate life each student receives a living wage and on qualification 300 roubles a month. It is impossible to translate that into our currency, because the exchange is artificial: for purchasing purposes I think one may regard one rupee as the equivalent of rather more than three roubles. The physician's wife might be getting a similar income, and he has not to bother about insurance, children's education or holidays: but he may not always have the same kind of family life as in India.

If, however, the present Soviet students are trained in our view imperfectly, this is to some extent compensated by excellent arrangements for post-graduate training. In the Soviet every doctor is supposed to have a post-graduate course of three to six months every three years. How this is arranged administratively I do not know: but I think the training is compulsory now, though it was not so last year. For post-graduate training there are special institutes, there being ten such places in the U. S. S. R.; but use is also made of the special hospitals for post-graduate training, for I saw post-graduates at work in the Tuberculosis Institute at Kharkov.

Such is a brief account of medical education under conditions that we may regard as a great experiment and one to be watched with interest. In India, I am sure we should be wrong to lower educational standards in any way in order to raise the numbers of graduates or licentiates; but I think we might do more to get many of our young doctors to work in country districts instead of spending their time in the overstocked towns.

II

Tuberculosis

A study of the anti-tuberculosis campaign in Russia is not only of interest but may give profitable lessons to our campaign in India. The Soviet results are remarkable, and if their figures are correct—I have no reason to doubt them, as where I could check them they tallied—then these results may cast doubt on what has been taught by some hygienists. It has been taught that the development of natural immunity in a population and improvement in its general social

welfare are the only important conditions that tend to a decrease in tuberculosis incidence and mortality. We are told that special anti-tuberculosis measures cannot take credit for the steady decline in mortality in Great Britain, for instance, from the year 1860, and the small rise that occurred in the war years is explained by the lowered nutrition of the people at that period. This last statement is doubtless true, but from a study of the Russian situation it would appear that not all the credit can be taken by improved housing, drainage and nutrition; but that some improvement at least is due to the special measures that attend an anti-tuberculosis campaign. For whereas the conditions of general hygiene and nutrition have improved in Russia since the Revolution they have not, I consider, improved so greatly as the tuberculosis mortality, nor did the improvement in these matters apparently start so soon as the fall in mortality did. The decrease of tuberculosis mortality in the Ukraine seems to have started from 1923, whereas the rehousing of the people did not get well under way until five years later when the first five-year plan started. About nutrition I cannot write with certainty; the food of the people is better now than before the Revolution, but in some intervening years one has heard of shortage of food and even of famine. Further, and this is perhaps the most important matter, the improvement in the tuberculosis outlook has taken place in circumstances when one might have expected an increase in the mortality. We have been used to point to the beginning of urbanization and industrialization in India as a cause of the probable, but unproven, increase in tuberculosis mortality there, and to the influx of a rural and in some cases primitive population to cities already overcrowded. But these things have also been going on in Russia and in much greater degree than in India. Before the war the population of Moscow was $1\frac{1}{2}$ millions: it is now $3\frac{1}{2}$ millions and many factories have been erected. In other cities, such as Leningrad, the increase of population is also large, though less proportionately than in Moscow. Billions of roubles have been spent on rehousing and the erection of apartment-houses still goes on; but there is still overcrowding, and the living conditions of very many are still unsatisfactory and unhygienic. One would have expected therefore the tuberculosis mortality in Russia to have increased since the Revolution, but the figures show the reverse. For some of the figures of former years I am indebted to Dr. Sigerist's book on *Socialised Medicine in the Soviet*: more recent figures I have obtained direct from the Soviet physicians. I cannot give figures for the whole country, but in 1913 the mortality from pulmonary tuberculosis in St. Petersburg (Leningrad) per 10,000 inhabitants was 28.6, in 1931 it was 16.3, and I was told that it is now 12.0. Similarly in Moscow in 1913 the rate was 22.6, in 1931 it was 11.6, and I was told it is now

between 10 and 12. For two large cities of the Ukraine the mortality per 10,000 from tuberculosis (I think this refers to pulmonary tuberculosis only) is thus recorded—

		1923	1927	1932	1937
Kharkov	..	17.0	14.0	13.3	12.0
Odessa	..	22.7	17.9	17.2	?

The mortality is still high compared to some other countries, but the decrease has been remarkably rapid. Further, the Soviet authorities have set themselves as part of the third five-year plan, which began on 1st January, 1938, to reduce the present tuberculosis mortality again by one half. It seems impossible to cause so sudden a fall in the death rate of a chronic disease. We are accustomed to see the mortality line on the graph fall in a gentle slope; but the progress hitherto has been so remarkable that we need not be surprised at a further considerable diminution of mortality.

Now to examine the main features of the campaign and the methods that are employed. The first thing that strikes one is the intensity of the attack on the disease, the large number of institutes, dispensaries, sanatoria, etc., and especially the large number of personnel engaged. According to Dr. Sigerist there are about 27,000 physicians employed in tuberculosis dispensaries and sanatoria: if they are all staffed on the scale of those I saw I can well believe it. I saw one tuberculosis dispensary in Moscow that had 25 physicians and there are 25 tuberculosis dispensaries in that city alone. All these 27,000 physicians have had special training: that is to say, one-quarter of the total number of Soviet physicians is engaged in purely anti-tuberculosis work. To staff a campaign in India on the same scale we should require over half a lakh of tuberculosis specialists. Apart from that number special tuberculosis training is given to all undergraduates, as it is in India, and at the institutes post-graduate courses of four months in length are given to 500 young doctors yearly. The institutions of various functions that are engaged in the campaign are:—

- Central Tuberculosis Institutes.
- Regional Tuberculosis Institutes.
- Sanatoria.
- Special Hospital Wards.
- Dispensaries.
- Night Sanatoria: Day Sanatoria.
- Labour Prophylactoria.
- Sanatoria Schools.

Some of these terms require explanation.

The functions of a *tuberculosis institute* are to direct the campaign in its area, conduct research, collect statistics, publish popular literature as well as scientific articles, advise and inspect the dispensaries in its region, give undergraduate and post-graduate instruction, and generally advise all units who consult it and with whose activities it is in constant touch. There is one central tuberculosis institute in Moscow that

acts as a general staff for the whole campaign, and Moscow also has a regional institute for its own district activities. There are eleven republics in the Soviet Union, exclusive of 17 small autonomous republics, and five of these major republics have their central institutes, while there are many regional institutes. They all have both laboratories and clinical departments. The central institute of the Ukraine, which I saw at Kharkov, had numerous laboratories and 250 beds, including several for children in a separate block. The cases were those of special interest or requiring some special treatment. There was no out-patient department, but numerous cases are sent for consultation, from dispensaries and factories, but all for some special reason.

Sanatoria are on the same lines as elsewhere and situated in attractive places remote from towns, such as on the shores of the Black Sea or in forests. I did not see one. There are not enough sanatoria beds yet, only about 40,000 at present. The number is to be increased largely in the present five-year plan.

Some, mostly open cases, are treated in *special wards* of a general hospital. The Soviet do not build many special tuberculosis hospitals, but prefer to send cases as much as possible to sanatoria. There is one tuberculosis hospital of 250 beds eight kilometres outside Kharkov.

As elsewhere the *dispensary* is the battle-front of the campaign, with this difference from common practice, that whereas in most other countries the dispensary is for diagnosis, prevention and propaganda only, in Russia the dispensary undertakes treatment as well. This is done also in India, and I have previously advocated it as the correct practice in India, whatever may be done in Europe. The dispensary I saw in Moscow had thirty beds, where patients may be kept for a few days for observation or after minor operations, such as pneumothorax, phrenic evulsion and even Jacobus' operations. That dispensary served a district of 300,000 inhabitants and had about 10,000 patients of whom it saw 500 daily. I believe there are about 800 such tuberculosis dispensaries in the Union altogether, and, in rural areas not populous enough to support one, a part of a general dispensary is adapted for tuberculosis work. Nevertheless, they said the number of dispensaries was still insufficient. As elsewhere the chief work is detecting early cases. The one I saw was evidently hard at work all day. Visiting nurses are attached to them.

Night sanatoria are rest-homes for tuberculous workers who are able to go to the factory, but are not yet fit enough for ordinary life. They are partly for early cases and for these form also a means of education, but mostly for ex-sanatorium cases as a means to leading them gradually back to normal life. They and the labour prophylactoria take the place that a Papworth or similar colony does elsewhere. An attempt was made to organize a Papworth in the Soviet

but was not successful: the patients would not stay.

As every factory in the Soviet works continuously night and day in three shifts, *day sanatoria* are similarly arranged for night workers. At a night sanatorium the patients arrive in the afternoon after work, have a bath, dinner and rest. They are then seen by the doctor and go to bed at ten. The system is said to work well and such temporary sanatoria are attached to dispensaries and sometimes to institutes. I saw also a day sanatorium for children suspected of possible early tuberculous infection. They were being sent home after a meal at 6 p.m. There are many such institutions in the cities.

The *labour prophylactorium* is another example of Papworth-like occupation, except that it is not a separate institution, but several large factories have a special workshop for cases of suitable type. Such cases are not put on the land, but in factories where they can be better supervised. If the patient is not equal to his former occupation, he is instructed in new work. Their working hours may be less and they have special dining rooms. The labour question looms large in Soviet consideration and much attention is paid to the working of these patients. Much of the tuberculosis research work published in the Soviet is concerned with the amount of work that can be got from these patients without doing them any harm.

I saw near Leningrad a *sanatorium school*, a boarding school where tuberculous children were instructed. Several of them were having pneumothorax treatment without interruption to their classes or their games.

There is a considerable amount of bone tuberculosis treated at many of the above institutions, and there are special sanatoria for children with bone tuberculosis. The physicians did not seem to take much interest in the question of its possible bovine origin, and I obtained only vague answers to my queries on this point in all the cities I visited. The most definite reply was that there was not much bovine tuberculosis in human beings, except for some cases of peritonitis in children. I was told also that primary abdominal tuberculosis in any form was uncommon, which is different from our experience in India.

Much use is made of B. C. G. vaccination. In some cities it is compulsory for all children who are likely to be exposed to infection, but it is not compulsory everywhere, though an effort is made to persuade the parents to consent and since the vaccine is given by the mouth there is usually no objection. Considerable benefit is claimed for this measure but it is still in the experimental stage.

Gold therapy is not much used and is regarded as still experimental. Otherwise treatment is on the usually accepted lines.

One interesting point is the publication of research work by Ukrainian physicians (Morosovski; Moutti; Ginsberg) to demonstrate

that tuberculosis workers are subject to real danger from infection from their patients. They have shown a comparatively large morbidity which, they say, cannot be explained by natural selection or by chance. This is contrary to what we have been taught hitherto. I call to mind some statistics of the nursing staff of a large chest hospital in London which demonstrated that the risk of these nurses was no greater than that of nurses elsewhere. Personally, I incline to think the Ukraine physicians are right. All those who have worked at tuberculosis must know so many cases of their colleagues and assistants who suffered infection as to seem beyond the usual proportion. At any rate the Soviet authorities are so convinced of this danger that they pay their tuberculosis physicians more highly than the others.

The Soviet Government evidently pay the greatest attention to the advice of health advisers and value them highly. I saw many other things of interest in the Soviet apart from tuberculosis

and apart from medicine at all. Perhaps the most remarkable fact I came upon was that prior to 1914 no less than 82 per cent of the syphilis in Russia was of extra-genital origin. It was only in minor part a venereal disease.

The Soviet physicians were everywhere most courteous in showing me their institutions and activities and I am satisfied I saw things as they usually and naturally were, while the guide-interpreters, who were ladies and sometimes doctors' wives, were most patient in translating my numerous questions and their replies.

On consideration, I conclude, although the vigorous anti-tuberculosis campaign with its educative propaganda and rehousing must certainly account for some of the striking decrease in tuberculosis mortality, that the most important factor to that end, although I have no direct evidence to that effect, must be better nutrition of the people. I cannot see how anything else can produce so marked an improvement with such rapidity.

Medical News

SUMMARY OF TUBERCULOSIS NEWS FOR THE MONTH OF NOVEMBER 1938

Post-Graduate Courses in Tuberculosis

(a) THE seventh post-graduate course in tuberculosis organized by the King George Thanksgiving (Anti-Tuberculosis) Fund was opened on the 14th November at the King Edward Medical College, Lahore. Fifteen doctors from Northern and Central India were selected from among 169 applicants for training. In opening the course, the Hon'ble Minister of Education, Punjab, referred to the collection of rupees four lacs from the Punjab in response to Her Excellency the Marchioness of Linlithgow's Appeal for the King-Emperor's Anti-Tuberculosis Fund. The opening address on 'the tuberculosis problem' was delivered by Colonel G. G. Jolly, C.I.E., V.H.S., I.M.S., Inspector-General of Civil Hospitals, Punjab.

(b) The King George Thanksgiving (Anti-Tuberculosis) Fund has decided to hold a medical post-graduate course in tuberculosis at the All-India Institute of Hygiene and Public Health, Calcutta, from 30th January to 25th February, 1939. Eminent tuberculosis specialists and medical superintendents of some of the tuberculosis sanatoria in India will deliver lectures on various aspects of the subject, in addition to practical demonstrations, etc.

Selected candidates will be paid by the fund single second-class return railway fares to and from Calcutta up to a maximum of Rs. 100 per head.

Her Excellency the Marchioness of Linlithgow's Appeal for the King-Emperor's Anti-Tuberculosis Fund
The 22nd list of subscriptions actually received up to 31st October, 1938, amounts to Rs. 1,66,313-14-11, which brings the grand total of collections to Rs. 61,91,251-15-6.

DRUG CONTROL IN INDIA. POOR QUALITY OF ERGOT PREPARATIONS. BIOLOGICAL LABORATORY'S INVESTIGATIONS. ALL-INDIA DRUG SURVEY

THE urgent need for proper drug standardization and for a comprehensive scheme of drug control has been painfully brought out by a recent investigation

undertaken by the Biochemical Standardization Laboratory, Calcutta, into the liquid preparations of ergot sold in the Indian market and in common use for medicinal purposes. This laboratory, which was established by the Government of India in Calcutta in 1937, as a first step towards tightening of control over the manufacture, importation and distribution in the Indian market of drugs inferior in quality and spurious in character, has since its inception been engaged in an all-India survey of the quality of drugs. Some of the findings recorded in this laboratory reveal a serious state of affairs regarding the quality of ergot preparations that are daily being used in India.

Chiefly used to stop post-partum hæmorrhage, an emergency condition where energetic treatment with fresh and potent ergot preparations is essential to save the life of a mother, the poor quality of liquid extract of ergot which the commonest preparation employed in hospitals and private obstetrical practice in India constitutes, therefore, a grave menace to maternal health, and is possibly also a contributory factor to maternal morbidity from a subinvolved and imperfectly contracted uterus.

Inferior drugs imported

Of 130 samples of ergot preparations of different types, e.g., liquid extract of ergot, ammoniated tincture of ergot, solid extract, and ergot powder, tested in the laboratory, 112 samples or 86.15 per cent were found much below strength, and in 58 or 44.61 per cent no active principles whatever could be detected.

Of the samples examined 103 were of indigenous manufacture and 27 of foreign make.

The causes underlying this state of affairs are not clearly understood. While the deterioration of the active principles of ergot in the hot and humid climate of India may be an important factor in bringing about the poor quality of ergot preparations, the opinion is expressed that it seems probable also that an inferior quality of both crude and finished preparations of ergot, unsaleable in their countries of origin due to stringent drug laws, is being purchased in India at a cheap price.

General low quality

That the results obtained from these investigations are representative of the general quality of ergot

preparations all over India will be evident from the fact that the samples subjected to analyses were obtained from practically all the provinces of British India through the surgeons-general, inspectors-general and other heads of medical public health departments. A few were obtained direct from the customs office, within a few days of their importation, while another group of preparations was picked up at random from the open market.

The standardization of the ergot preparations was carried out by pharmacologists and pharmaceutical chemists working in close co-operation. The 'colorimetric method' of assay described in *British Pharmacopœia* 1932, with the modification subsequently described in the Addendum to the *British Pharmacopœia* 1936, was generally employed and, wherever necessary, the results were checked by the 'rabbit-uterus' method of biological assay.

Results analysed

The following is a tabular statement of the analysis of the quality of ergot preparations on the Indian market:—

Analysis of the quality of ergot preparations on the Indian market

Nature of preparations tested	Total number	ORIGIN		PREPARATIONS BELOW STRENGTH			
		Indigenous	Foreign	Total number	Per cent	No active principle	
						Number	Per cent
1. Liquid extract of ergot ..	108	86	22	96	88.88	54	50.0
2. Liquor ergot fortis ..	8	8	..	5	62.5
3. Ergot prepared ..	8	5	3	6	75.0
4. Ammoniated tincture of ergot ..	2	2	..	2	100.0	2	100.0
5. Ergotinine citrate ..	2	1	1	2	100.0	2	100.0
6. Ergot powder ..	1	1
7. Solid extract of ergot ..	1	..	1	1	100.0
	130	103	27	112	86.15	58	44.61

especially during the war, and now there are at the Madras and Bombay Depôts two modern up-to-date factories, employing Indian labour capable of supplying all government institutions in India with drugs and preparations of *British Pharmacopœia* standard.

At each of these factories there is employed a highly qualified advisory chemist, whose duties include the analytical examination of every preparation made in the depôt factory and all supplies received from outside to see that they are up to the prescribed standard.

Purchases in India

Further, as soon as it is found that a preparation of the required standard can be obtained in India at a rate not more than the cost of manufacture in the depôts, the manufacture of that particular item is discontinued and it is purchased locally. More than half the amount provided for purchase of stores is in this way spent on purchases made in India. Stores worth Rs. 11,52,131 were imported in 1936-37, while stores worth Rs. 14,14,796 were purchased in India during the same period.

DRUG MANUFACTURE IN INDIA. MEDICAL STORES DEPARTMENT'S PIONEER WORK

It is not widely known that the Medical Stores Department has done pioneer work in the manufacture of drugs in India.

There are many preparations which are made exclusively by the department. For example, in Madras are made the four preparations of oleum hydnocarpus, used in the modern treatment of leprosy, and it is believed that this is the only source in India from which these preparations can be procured at a reasonable rate.

There are four Medical Store Depôts, located at Madras, Bombay, Calcutta, and Lahore, respectively, administered by the Director-General, Indian Medical Service, on behalf of the Government of India, Defence Department.

Up-to-date factories

The depôts were originally established to ensure the supply of drugs, instruments, and appliances, of uniform quality and pattern for the Army in India. In course of time their sphere of activity was extended and the civil medical institutions turned to them as the most reliable source of supply.

The stores were, at first, only distributing centres. It was, however, discovered that some of the drugs could be more economically manufactured in India than imported from abroad, and in consequence depôts undertook to do pioneer work in manufacturing. The number of items manufactured gradually increased,

A vital function

It is not the policy of the government to compete with private enterprise, nor is it the intention to make a profit from the Medical Stores Department, although it is desirable that it should be as nearly self-supporting as possible. Private institutions are not encouraged to obtain their supplies from the depôts, but the experience of the past has proved that the department was able to make good the deficiencies required for civil purposes and which were due to the failure or irregular supply of imported drugs.

The Medical Stores Department therefore fulfil a useful and necessary function, which may in time of crisis become vital.

PREVENTION AND CURE OF DISEASE. NEED OF CO-ORDINATING MEDICAL AND PUBLIC HEALTH DEPARTMENTS

THE activities of those responsible for medical relief and prevention of disease are so closely inter-related that it is impossible to draw any sharp distinction between them, and the consequent necessity for co-ordinating Government Medical and Public Health Departments is being increasingly felt.

Prevention better than cure

The Central Board of Health at its first meeting passed a special resolution which stressed the need for co-operation between these two departments, and recognizing the important position which prevention occupies in every phase of medical practice, both the

Medical Council of India and the General Medical Council of Great Britain recommend that 'throughout the whole period of study the attention of the student should be directed to the importance of the preventive aspects of medicine'.

In most countries all branches of medicine are administered by one Health Ministry with separate higher directing staffs, but India is peculiar in the extent to which in some areas the activities of medical and public health departments have been separated or in a few cases even divorced from each other.

The prevention of disease has come to be universally recognized as being the chief aim of medical work and most of the administrative medical officers are now enthusiastic advocates of disease prevention; indeed some of them have been specialists in public health for the greater part of their previous service. All of them state that they are prepared to co-operate with the directors of public health and to insist on a similar co-operation on the part of the members of their staff.

This combination of effort does not mean the swallowing up of one department by another but only that, whenever it is in the interests of efficiency and economy, the medical man ought to engage both in medical relief and public health work.

In the district

While a satisfactory degree of liaison exists between the directors of medical and public health departments, it is in the district, in the sphere of the civil surgeon and the district health officer, that health presents its most important problems and where there is the greatest need of co-operation. Separate higher directing staffs technically qualified, co-ordinated by an administrative head, are essential for efficiency, but when we come down to smaller district units, such as the village dispensary, it is certain that India can never afford to maintain two experts for each small centre of her population.

The dispensary doctor

As long as the ideal is unattainable for financial and other reasons, the most promising line to follow is that of the District Health Bureau recommended and outlined by the Central Health Board, on which the civil surgeon and the public health expert of equal standing can co-ordinate all their activities.

Further the dispensary doctor must be brought more intimately into the local health picture and his usefulness increased by improving the teaching of hygiene and public health in medical schools and colleges. In their knowledge of the people and the confidence in them, gained by frequent contact, the civil surgeon

and the dispensary doctor are valuable assets which should be fully utilized.

THE ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION

THE first general meeting of the Indian Division of the Royal Medico-Psychological Association will be held on 23rd and 24th January, 1939, at the Punjab Mental Hospital, Lahore, under the chairmanship of Lieutenant-Colonel C. Lodge-Patch, M.C., I.M.S., Medical Superintendent. The Governments of India and Ceylon as well as the provincial Governments of Assam, Bihar, Bombay, Central Provinces, North-West Frontier Province, Punjab and United Provinces have kindly agreed to grant members employed under them special leave and travelling expenses to attend our meetings triennially. The Government of Madras have sanctioned only the concession of special leave for one officer to be selected by the Surgeon-General. The Governments of Bengal, Orissa and Sind have no member working under them but are willing to consider the matter when necessary. Members who wish to avail themselves of the facilities granted by their respective Governments should apply to them at once through the proper channel for permission to attend the meeting. This notice is issued so early to give every member sufficient time for this purpose.

On 23rd January, 1939, at 8 p.m. the Association Dinner will be held. All attending members are specially requested to join the dinner. The dinner fee of Rs. 8 should be sent before 10th January, 1939, to Lieutenant-Colonel C. Lodge-Patch, M.C., I.M.S., Medical Superintendent, Punjab Mental Hospital, Lahore, so that he may be able to make the necessary catering arrangements.

It is hoped that many members will contribute interesting and instructive papers to be read at the meeting. Such papers should be of a practical rather than an academic character. The principal object of the meeting is to provide an opportunity for psychiatrists to pool experience and to exchange ideas in order to improve psychiatric work in this vast country. It is not possible to allot more than 20 minutes for the reading of any paper and 5 minutes will be given to each speaker in the subsequent discussion. Those willing to read papers are particularly requested kindly to forward to Dr. Banarsi Das, Mental Hospital, Agra, a precis of the same by 20th December, 1938, at the latest.

Dr. C. J. Thomas, an eminent member of the Association in England, is coming out to India and is expected to bring out for us some token of goodwill from London headquarters to be personally presented to the new Indian Division at its first meeting at Lahore.

Current Topics

Some Recent Advances in Medical Diagnosis and Treatment

By A. H. DOUTHWAITE, M.D., F.R.C.P.

(Abstracted from the *British Medical Journal*, Vol. I, 28th May, 1938, p. 1143)

MEDICINE has made such gigantic strides in the last few years that to cover the field would be a task beyond my powers. I shall limit myself to those recent advances with which I am chiefly familiar. Most of these relate to the digestive tract.

SIALOGRAPHY

The radiographic demonstration of the ducts of the parotid and submaxillary glands has been made possible by the injection into them of substances opaque to

x-rays. By the introduction of lipiodol into the parotid duct the outline of the main duct and its branches can be demonstrated and, when infection occurs, various abnormalities such as spherical dilatation, comparable to that seen in bronchiectasis of the lung, can be demonstrated. Symptoms and signs of recurrent pyogenic parotitis fully investigated by examination of the saliva and also by sialography have been summarized. It usually starts with a feeling of fullness in the region of one parotid and then slight swelling. Attacks may be initiated by a meal. The gland gradually enlarges, reaching its maximum within a few hours up to twenty-four, and subsides over a course of several weeks. During subsidence a foul taste may be experienced, and examination may reveal muco-pus oozing from the duct. After a period of relief the whole process is repeated. It is interesting to note that the ratio of females to males is 8 to 1. So far as

physical signs are concerned the gland is easily palpable, not uncommonly tender, and, with acute exacerbation of the disease, fever, increase of swelling, and well-marked tenderness are present. The saliva, instead of being clear, contains numerous flakes consisting of shreds of mucus with pus cells, epithelial cells, and micro-organisms. I have notes of seven patients whom I have seen with this disease, and five of them have apparently recovered completely as the result of massage to the parotid, directed especially along the line of the duct, and also diathermy. In one case of submaxillary gland infection its removal resulted in entire disappearance of symptoms. In the submaxillary gland case and three of my parotid patients the outstanding symptom was, in point of fact, that of *soreness of the tongue*, and owing to the great frequency with which one meets this most troublesome symptom in practice the possibility of a chronic infection of one or other of the salivary glands should certainly be borne in mind.

GASTRIC AND PEPTIC ULCER

One cannot obtain a clear idea of the advances made in the diagnosis and treatment of these conditions without briefly reviewing the last twenty years, or even more. It was Moynihan who was responsible for describing the symptoms of duodenal ulcer and placing that condition in the medical map as a diagnosable entity. In 1921 Bennett and Ryle published the result of their investigations of a hundred healthy students by means of a fractional test meal, and thus applied a further stimulus to gastro-enterology. They showed that 20 per cent possessed a degree of free acidity which fell outside the mean curve. Of this 20 per cent half were hyperchlorhydric and half were hypochlorhydric or achlorhydric. It was about this time that they and other workers popularized the alkali treatment of gastric and duodenal ulcer. MacLean and others wrote on the cure of gastric and duodenal ulcers by intensive alkaline treatment. They referred to the already well-known fact that suitable alkalis, rest, and diet would cause a disappearance of symptoms, and produced various radiographs showing the disappearance of ulcer craters. The investigations of these patients were not, however, repeated after a long enough interval to justify the assumption that they were cured.

We now know that a great number of methods of treatment will result in the apparent cure of an ulcer if judged purely by x-ray appearances. I have produced equally striking effects with histidine in patients who have had no other treatment, but am quite satisfied that, in spite of the relief of symptoms, the ulcers were not cured. This drug, which has been used largely in the form of a preparation called 'larostidiu', is injected intramuscularly daily from fifteen to twenty doses. Numerous and conflicting reports have appeared as to its value. The general opinion of critical observers is that it seems to have some effect in aiding the healing of ulcers, but it is not permanent, and certainly the preparation cannot replace the more orthodox methods of therapy. I began to doubt its efficacy when I followed up histidine-treated patients for a few weeks subsequent to the discontinuation of treatment. In every case a relapse was noticeable, not only from recurrence of symptoms but also from x-ray appearances within five weeks. No doubt the mere fact of relapse is a strong point in favour of the histidine having done some good, but, on the other hand, it is highly improbable that anything approaching healing could have been produced with such an early return of all the signs and symptoms. There is no evidence that ulceration in the human being is due to deficiency of histidine, and there seems, in point of fact, no convincing experimental work to justify its use. If a series of patients are treated with an intensive alkali and dietetic regime and compared with those treated with histidine it will be found that there is very little difference in the immediate recovery percentage. On the other hand, ~~in~~ histidine-treated patients relapse more readily ~~and~~ ^{or} ~~pior~~ ^{more} rapidly than those treated by diet ~~and~~ ^{and} ~~therapy~~ ^{therapy}. Gastroscopy has already taught us

that large craters as seen by x-ray seldom seem so deep when observed by direct vision. The apparent depth is produced not only by swelling of the mucosa but by contraction of the underlying muscularis.

ASSOCIATIONS OF GASTRO-INTESTINAL DISEASE

The remarkable discoveries of Minot and Murphy relative to the treatment of pernicious anæmia, and the more recent work of Castle in explaining the association of achylia with this hitherto fatal disease and with sub-acute combined degeneration of the cord, have given a tremendous forward impulse to the study of gastro-intestinal disease and its relation to more remote systems of the body. I drew attention to an interesting group of hitherto unexplained cases of polyneuritis, sometimes of extreme severity, all of which appeared to be associated with disease of the stomach leading to achlorhydria or achylia, and termed these gastro-genous polyneuritis. In view of Castle's recent work it may well be that they are actually examples of European beri-beri, for it has been shown that in conditions of gastritis and achylia the absorption of vitamin B₁₂ may be deficient, and that an adequate supply of this substance is capable of curing certain types of neuritis, especially alcoholic neuritis, even though the original aggravating factor is still operative.

through the original aggravating factor is still operative. One observer preached unheeded for many years the doctrine of chronic gastritis. He studied stomachs preserved by the injection of 10 per cent formalin solution through the abdominal wall into the peritoneal cavity and into the stomach, and, following that investigation, he advanced the study of gastric pathology by the recognition of chronic gastritis and also of the acute variety. Whether one has to assume that all cases of achylia are the result of chronic gastritis is to my mind quite another matter. This has been accepted as a teaching during the last few years on incomplete evidence, for although it is clear that chronic gastritis might well be expected to produce atrophy of the mucosa in time, it is by no means certain that all conditions in which gastric atrophy is present have been preceded by an inflammatory state—in short, by gastritis. One must be cautious before jumping to this conclusion, particularly when it is borne in mind that the incidence of achlorhydria and achylia rises steadily with age. It seems on the face of it unlikely that an inflammatory condition of the stomach would attack the populace with such regularity. On the other hand, if achylia is due to a gradual degeneration, such as occurs in other structures with advancing years, the findings would be understandable. The point is of importance because if Hurst's view is correct, that gastritis is the precursor of achylia, and gastritis always precedes the development of carcinoma of the stomach, except in ulcer cancer, it should be possible materially to reduce the incidence of stomach cancer. If, on the other hand, achylia is frequently not the result of inflammatory changes, the whole supposed association between achylia, gastritis, and carcinoma becomes at once subject to considerable doubt. Cases of cancer of the stomach where test meals taken at intervals have shown the presence of a carcinoma and a free acidity which has steadily diminished have been reported. This would suggest that the cancer was responsible for the fall of acid. The most that can be said at present is that, although on theoretical grounds it is probable that the gastritis-cancer sequence is true in a proportion of cases, it must not be regarded as an invariable association, even apart from those cases of cancer which do sometimes arise in chronic gastric ulcer.

NON-ULCERATIVE HÆMATEMESIS AND MELÆNA

In using the term 'non-ulcerative' I mean to imply that the cases about to be described are those in which profuse hæmorrhage has occurred and shown itself either as melæna or as hæmatemesis, or both, and in which there has been no preceding history of ulcer and where the most careful investigations have completely failed to reveal the presence of an ulcer after the hæmorrhage. Furthermore, the subsequent history of these patients

has been quite unlike that generally associated with peptic ulcer.

My attention was first drawn to the possibility of severe hæmorrhage occurring in the absence of a readily demonstrable disease in the stomach or duodenum by a patient under my care at Guy's Hospital who had been twice admitted on account of recurrent severe hæmatemesis. He gave no history of indigestion. Melæna persisted for two or three days only and then cleared up. Several x-ray examinations revealed no disease. A fractional test meal showed achlorhydria and a great excess of mucus in every specimen. The case was presumably one of gastritis. With rest in bed, a non-irritant diet, and gastric lavage he rapidly improved. A further test meal revealed a return of free hydrochloric acid and no excess of mucus. There has been no recurrence of symptoms after five years.

A man aged 50 was seen by me three years ago on account of severe hæmatemesis and melæna, again with no preceding history of indigestion. Physical examination was negative, except for hæmoglobin of 52 per cent and heavily infected teeth. He was treated with soft diet and rest in bed, but had a further severe melæna. His doctor then called in a surgeon, who performed a laparotomy and found no abnormality. The patient recovered in spite of this. A test meal revealed exactly the same state of affairs as in my previous case.

The next three patients were those with hyperchlorhydria. In one there was a history suggesting a duodenal ulcer, but this was not demonstrated by the most careful and repeated x-ray investigations, and the profuse melæna for which he came in cleared up in two days. The other two patients are of considerable interest, since both of them were doctors and reliable witnesses. The first consulted me because he had noticed black stools and had felt giddy. He said that he had been perfectly well until a few hours after being at a cocktail party, where he had had only one cocktail but had eaten a large number of salted almonds. His theory was that these had scratched his mucosa. Investigation in a nursing home revealed the hyperchlorhydria so common in doctors. X-ray examination four days after the melæna showed a normal stomach and duodenum. Occult blood had left the stools in three days. The patient has been back at his busy practice for over two years since, and has taken no precautions: he has smoked and has taken alcohol without any further trouble.

The last example was that of a doctor who, on account of supra-orbital neuritis, kept himself going in his practice by taking aspirin. This had been proceeding for ten days when one morning he awoke with pain and took two aspirin tablets without water or milk, as had been his custom hitherto. A quarter of an hour later he felt a slight epigastric pain; the same day, four or five hours later, he felt faint and had colic, and soon passed stools containing a little visible blood and a large amount of tarry material. The value of this instance is that he had his alimentary tract examined by x-rays and a fractional test meal and a blood count done four or five days before this occurred, and, apart from a hyperchlorhydria, he was shown to be normal. The investigations were purely precautionary, as he had reached middle life (41 years). After the melæna, which lasted for three days, his hæmoglobin was 58 per cent. In spite of this he carried on at work, and made a complete recovery. When radiographed twelve days after the bleeding, again no abnormality was found. He had never had any symptoms of indigestion, and has had none since, although two years have elapsed.

The last two cases, I believe, illustrate the susceptibility of the gastric or duodenal mucosa, especially in the presence of a high acid, to what are regarded as minor sources of irritation—in the one alcohol, or possibly salted almonds, in the other free acid liberated from aspirin.

Clearly, it is of practical value to realize that profuse hæmorrhage may occur as the result of chronic gastritis on the one hand, or comparatively slight trauma in the presence of hyperchlorhydria on the other hand, otherwise these patients might well be condemned to

irksome and superfluous restrictions. The more our knowledge of the stomach increases, the greater does the value of special methods of investigation increase. It is only by these that we can be certain of such diagnoses as gastritis and mucosal atrophy. Many people presenting test meals of a type suggesting gastritis have no symptoms whatsoever. In the past it has been assumed that gastritis was present if there was hypochlorhydria or achlorhydria, associated with an excess of mucus. On the other hand, the finding of hyperchlorhydria, which is seldom associated with an excess of demonstrable mucus, was not thought necessarily indicative of gastritis. Too much importance has been attached to what has been regarded as an excess of mucus in the past. The less the acid secreted, the more will the mucus appear to be, although there may be no true absolute increase. Conversely, in highly acid specimens, mucus, when present, is masked and is very difficult to detect. The most obvious appearances of gastritis, as seen through the gastroscope, are usually to be found in a hyperchlorhydric stomach in which test meals reveal no mucus. In short, a hypertrophic gastritis that is very liable to superficial erosions and bleeding will give a test meal of hyperchlorhydria more often than not. If in cases of achlorhydria or hypochlorhydria there is apparently a great excess of mucus, so much so that it is difficult to obtain specimens through the tube, and if in addition blood or pus cells are detected microscopically in the test meal deposits, and again if the test meal has an unpleasant smell, it is probably correct to assume that chronic gastritis is indeed present.

The value of the *gastroscope* lies mainly in three directions: (1) Giving a clear view of the gastric mucosa, from which one can say with some degree of certainty that gastritis is or is not present. (2) Indicating whether an ulcer which has apparently healed, according to occult blood tests and x-ray examination, has in fact healed or not, and it requires many more weeks of treatment after the signs are absent before sound healing has occurred. (3) To determine whether an ulcer is malignant. A malignant ulcer can occasionally be recognized as such, when x-rays have failed, by observation of its irregular edge.

X-rays.—The combination of the use of small quantities of barium emulsion smeared over the stomach and duodenum and the development of apparatus which allows of aimed exposures, if necessary with compression, make such an advance in radiographic technique that, given enough experience in interpretation, there is seldom any possibility of error in the diagnosis of peptic ulcer, or genuine as opposed to imaginary disease of the appendix. The only common mistake is to diagnose gastritis too readily, but this aspect will gradually be checked by the extended use of the *gastroscope*.

A most important contribution to gastro-enterology has been made in recent years. Immediately after death from *pernicious anaemia* the stomachs were fixed by the introduction of formalin through a stomach tube. Microscopy showed that the characteristic lesion was one of atrophy of all the stomach coats in the region of the fundus and the body mucosa. The pyloro-duodenal region, which was hitherto supposed to be responsible for the production of the intrinsic factors necessary for the health of blood and spinal cord, was quite normal. Furthermore, *there was nothing to suggest that inflammation—that is, gastritis—had preceded the atrophy*. Gastrosopy confirms the localization of the trouble.

Fifteen years ago, when the orthodox treatment for gastric and duodenal ulcer was prolonged rest in bed and two-hourly feeds of milk and milky foods until the stools became free of occult blood, I abandoned this procedure in favour of a liberal though soft-diet, allowing milk, cereals, bread-and-butter, honey, fish, and egg, and purée of fruit and vegetable, after one week of rest in bed on milk only. I have had no reason to regret it. I had not the strength of my convictions when dealing with cases of hæmatemesis until reading of the most impressive series produced by Meulengracht,

who gave patients exhibiting hæmatemesis and melæna a liberal diet, including even meat, provided the food was soft and the solid food was served as purée, with the most excellent results. He points out quite rightly that it is desirable that the stomach should not be empty of food and thus contain free gastric juice, which may be highly acid and therefore detrimental to the ulcer which is bleeding. Furthermore, the prolonged starvation of the patient, and even deprivation of an adequate amount of fluid, which was so common in the past could only give rise to anxiety, restlessness, and diminishing recuperative powers. His method of feeding has now become fairly general in our hospitals, and the claims have been fully vindicated.

REGIONAL ILEITIS

Localized inflammation of the small intestine has recently been holding the centre of medical attention. Some observers reported thirteen cases in which it was in the terminal foot of the ileum. It appeared to begin in the ileo-cæcal valve, and produced ulceration and destruction of the mucosa with thickening and inflammation of the other coats and considerable narrowing of the lumen. Abscesses and fistulae were reported. Since that time it has become clear that the condition may occur not only in the ileo-cæcal region but also at other points in the course of the ileum. Microscopically the lesion is seen to consist of a benign nodule, often presenting giant-cell systems, and thus giving rise to the mistaken assumption that the condition was one of tuberculosis. This has been disproved not only by microscopical examinations but also by guinea-pig tests. The symptomatology is a varied one, but with adequate care it is probable that many cases can be diagnosed before operation. The picture may be like that of ulcerative colitis, with diarrhoea, pain, and fever; or again, perhaps more frequently, there is central abdominal pain and recurrent distension of the abdomen, gradually giving rise to a permanent picture of chronic intestinal obstruction. By this time a mass can often be palpated in the right iliac fossa or elsewhere in the abdomen. Loss of weight and anaemia are also fairly constant features. A sudden attack of pain, with tenderness and some rigidity in the right iliac fossa, has often led to the removal of a completely harmless appendix. This should be taken as a warning against the employment of minute incisions for the removing of an appendix, when a larger one would have brought into view the diseased area of the bowel. If found in the early stages the treatment is satisfactory, and consists of resection of the affected portion. X-rays will help in the later stages by showing a filling defect and partial obstruction of the ileum.

INTRATHORACIC DISEASE

The biggest advance in the diagnosis of pulmonary disease is due to the more general appreciation of the value of the bronchoscope. The discovery of a small carcinoma of a bronchus is thus made possible; it may explain the presence of a lung abscess, the persistence of a cough, or even the sudden development of auricular fibrillation or flutter in a hitherto healthy patient. Why this remarkable association exists is still a matter of doubt. Now that surgery no longer shudders at the removal of a lung such early diagnosis is of very real importance.

Tomography allows of the taking of x-ray pictures of the lungs in different planes, while the other planes are sufficiently suppressed as not to interfere with a clear visual examination of the area inspected. This is particularly helpful in relation to cavities, whether tuberculous or those arising from non-tuberculous abscesses.

O'Shaughnessy's cardio-omentopexy for angina pectoris and persistent disability from cardiac infarction is the outstanding achievement of present-day surgery. The balanced judgment of physician and surgeon in choosing suitable cases of coronary disease is an essential to success.

PHARMACOLOGICAL ADVANCES

Of *prontosil* and its derivatives so much has been written lately that it would be pointless for me to do more than pay homage to this remarkable drug. The hæmolytic streptococcus, the *Bacillus coli*, the gonococcus, and probably the meningococcus are all susceptible to its influence, the first, however, far and away the most constantly so. Likewise of *gold* in the treatment of rheumatoid arthritis I shall say little, except to emphasize the fact that it is of much greater value in treatment than any preparation used hitherto; but it also carries with it many dangers.

Eumydrine (atropine methylnitrate), the dose of which is a sixtieth to a thirtieth of a grain, is a valuable anti-spasmodic, and less poisonous than atropine sulphate. It appears to have revolutionized the treatment of congenital pyloric stenosis in infants and converted it into a medical rather than a surgical problem, to the benefit of the infants.

A valuable addition to our pharmacological resources is *zinc-prolamin-insulin*. The object of this preparation is to produce an insulin which is absorbed slowly and will therefore have its action spread out more evenly throughout the day, and thus approximate as closely as possible to the normal production of insulin by the pancreas. The action starts in about nine hours and reaches its maximum in fifteen to twenty hours after injection. A single administration of ordinary insulin and the zinc preparation in the morning may thus suffice for daily treatment.

The success of *measles convalescent serum* was so great that in an epidemic it was often impossible to obtain supplies. This difficulty has been overcome in the most surprising way by the finding of an effective anti-measles *placental extract*. A dose of 5 c.cm. at the first sign of pyrexia, headache, or Koplik's spots will either prevent the rash entirely or render the disease of trivial severity. Smaller doses given earlier in the incubation period will have a similar effect. When we think of the frequency and severity of complications and sequelæ of measles it is clear that this discovery is of the greatest benefit to mankind.

Endocrines.—The development of endocrinology has already led to therapeutic results that are little short of startling. One can safely predict the profound effect it will have on medicine of the future, for we are no longer employing foreign substances to influence body activities but rather the very essences of the mysterious life forces. Already we can alleviate the mental and physical disturbances of the menopause with oestrin; we read of virility given to eunuchs with testosterone; and before long I hope we shall have means to control the obesity of pituitary or hypothalamic dysfunction. Yet we must progress cautiously and sift the evidence of efficacy with care lest endocrinology fall into the disrepute so justly meted out to wholesale vaccine therapy and other vogues. Nowhere is this more important than in dealing with male impotence acquired after a period of normal function. So often the cause lies in the mind, and its cure is suggestion. The work on the efficacy of hormones in relation to absorption rate has been summarized revealing the remarkable fact that the more complete purification of the essential extract results in reduced effectiveness on administration. This is due to the hormone being too rapidly absorbed. To counteract this tendency such combinations as testosterone propionate or oestradiol benzoate have been devised.

The Treatment of Retention of Urine

By A. WILFRID ADAMS, M.S., F.R.C.S.

(Abstracted from the *Medical Press and Circular*, Vol. CXCVI, 15th June, 1938, p. 524)

It is easy to picture the derangement in a sufferer from acute retention. But, to diagnose which of the numerous underlying causes is responsible for his urgent state, to determine the best plan of treatment and predict his probable future often calls for sharp wits.

RENAL RETENTION

At the outset it is interesting to widen our terms of reference and, interpreting the title literally, consider briefly unilateral acute retention in one of the renal tributaries of the bladder. Here, as elsewhere, the impasse may arise suddenly in the previously healthy or acute may supervene on chronic obstruction. In either case, too, it may pass or persist. The resulting clinical picture is renal colic, a disturbance so intense and shocking because in it a richly innervating gland is suddenly distended. The patient writhes in agony when blood-clot, stone or necrotic fragments choke the ureter or when its lumen is closed by twists, kinks or supervening swelling in acute infection. The solution of the problem demands more than a few attendances and injections of morphia and atropine. It is our duty, even if the usual relief follows, to have a full urological investigation to elucidate the underlying cause or, when sedatives fail, to summon a surgeon versed in the subject. He may save further damage by threading a catheter past the obstruction and restoring renal outflow, drain or remove a progressive pyonephrosis in its inception or find signs of sinister import such as tuberculosis or malignant disease. Renal colic is a savage warning and to ignore it may be to miss a golden opportunity of taking a terrible disease in time.

THE SIGNS OF ACUTE RETENTION

Acute retention in the bladder, though less shocking than in the renal pelvis, is more serious because it dams not one-half but the whole urinary excretion. It threatens the life of the patient and not that of one kidney only. The patient has a typical pain, unless the retention is due to paralysis. The tender, ovoid, but not always symmetrical suprapubic swelling can usually be defined and found dull on percussion. In some cases its contour is obscured by overlying fat or muscle guarding, or, rarely, appears duplicated owing to a large diverticulum. Confirmation comes with outflow of the urine and disappearance of the swelling, if a catheter is passable. When the bladder is found empty the diagnosis is changed to 'anuria'.

The catheter test

In the usual case an attempt at careful catheterization will greatly help in diagnosis as well as being, when successful, a boon to the patient. Whether the obstruction is in front of or behind the triangular ligament can be gauged by this means, and useful information is gleaned from an examination of the urine, if obtainable. Obviously it does not apply in such cases as phimosis, acute gonorrhoea, vulvo-vaginitis and reflex retention, which may be rectified by other means.

Finally, with the help of general clinical examination, including that of the nervous system, a doctor is enabled to determine the cause with sufficient accuracy in the majority of cases. Cystoscopy and skiagraphy are useful refinements in some instances and essential steps in the diagnosis of not a few.

Ætiology and treatment

The causal conditions group themselves under two main headings, local and nervous.

Local. In the male

(a) In infancy occur congenital phimosis, paraphimosis, valve formation in the prostatic urethra and impacted calculus. The remedies are obvious, and when medication, a hot bath or catheter fail, appropriate operation will succeed. The boy with mucosal valves in the prostatic urethra has already bilateral hydronephrosis from chronic retention. Treatment is for the specialist, and prognosis guarded.

(b) In the second decade additional factors may develop, foreign bodies may have been inserted or gonorrhoeal infection contracted and caused swelling or abscess of the prostate. This yields to hot baths or sedatives, but occasionally a gentle catheter is required

(c) It is in the adult male that the disease is chiefly found.

1. Hematuria may occur from injury to the kidney or from renal, vesical or prostatic tumour or following prostatectomy by the open or endoscopic operation. Such hæmorrhage often abates by an irrigation and in-dwelling catheter which later allows deliberate attack on the cause. It occasionally fills and clots in the bladder. This defies the expulsive efforts of the patient and adds to his afflictions that of acute retention. Urgent evacuation of the massive clot is compulsory, as are continuous irrigation of the bladder, drainage or, even, prompt removal of the offending prostate or kidney when hæmorrhage is otherwise uncontrollable.

2. Impaction of a stone is the common cause of sudden interruption of normal outflow. There may be a preceding history of renal colic or transient dysuria and it is usually readily diagnosed. When, however, the stone is in the posterior urethra or meatus it is readily dislodged into the bladder by a catheter with effectual relief and without the doctor detecting its causal presence. The patient is delighted enough, but the doctor mystified, unless he discreetly resorts to radiography and cystoscopy. Without extraction or litholapaxy the trouble will recur, and the patient's confidence be shaken.

A stone lodged in the anterior urethra is palpable. If it cannot be coaxed out or back into the bladder, it demands external urethrotomy. It is wise to exclude likely calculous companions in the upper urinary regions by skiagraphy.

Since sudden checking of a free flow and retention are associated with two other conditions, it is well to refer to them here. When a papilloma arises from the trigone, its fronds may be carried by the outflowing current of urine into the urethra, suddenly stopping the stream. A loose blood clot may do the same. Cystoscopy is required for their diagnosis and treatment.

3. Stricture of the urethra follows trauma or venereal disease. The latter is less likely in these days with the provision of free efficient clinics, but still goes on to acute retention at times and occasionally surprises the doctor in the elderly male. It is well, if gentle efforts, hot baths and sedatives fail, to arrange for an anæsthetic (spinal is appropriate) and to be prepared for the worst. We may find a case of stricture or multiple stricture permeable to a filiform bougie but no more. It is best to be content and tie it in for the patient to pass water alongside it for a few days. Thereafter routine progressive dilatation will be possible. If the stricture defies even a filiform bougie, supra-pubic puncture with a slender trochar and cannula gives temporary relief. The cannula, or a small catheter threaded through it into the bladder drains it for a few days, and with the relief of tension and oedema in the urethra, penile instrumentation may then succeed. The alternative is external urethrotomy (Wheelhouse) which allows a catheter to enter the bladder after cutting through the stricture. Cystitis, rigors and even fatal ascending pyelonephritis may ensue. Epithelioma occurring independently or supervening at a stricture may occlude the urethra.

Extravasation of urine

Here, mention of the deadly menace of urinary extravasation needs emphasis. It is one of the most fatal dangers in acute retention from stricture. Even when clean urine escapes from wounds of the bladder a serious cellulitis or peritonitis will ensue, but the process is apt to be somewhat insidious and take a day or two in declaring itself. If, owing to the unrelieved acute retention, heavily infected urine finally bursts through the dilated and ulcerated urethra proximal to a stricture, intense pain and virulent cellulitis result. The trouble spreads rapidly and may quickly overwhelm the patient. Prompt supra-pubic drainage does best by diverting the stream and is combined with incisions to drain the sodden tissues around the public region, the stricture being cured later.

Post-prostatectomy stricture appears at varying intervals after what has often appeared a perfectly successful operation, and sometimes causes acute retention. Diagnosis is almost automatic but permanent cure sometimes necessitates reopening the operation wound, if the scar at the bladder neck resists instrumentation. Such a calamity is less likely if precautionary sounds are passed before the patient leaves the surgeon. The doctor should observe the stream at monthly intervals for a time, and warn the patient to report any suspected diminution in outflow.

4. In the males over fifty and occasionally before, prostatic tumour is the common cause of acute retention. It is not till the soft catheter reaches the bladder neck that resistance is felt but, usually, a little pause and gentle pressure overcome it. The prudent doctor will let the expert take charge in stubborn cases rather than risk complicating the case by hæmorrhage and sepsis from unskilful efforts with stiff catheters. The cancerous gland is apt to be harder to feel and to penetrate. A tale of prostatic dysuria and the clinical findings are confirmatory. Although no swelling of the gland is felt per rectum, it may still be causing obstruction by fibrotic contracture at the bladder neck.

Before embarking on first-aid the doctor must decide whether the case is one of sudden distension of the bladder, or of acute supervening on chronic retention. With the latter is met the giant bladder and the pain is apt to be paradoxically less the greater the distension. The long history of ineffectual frequent micturition and the symptoms of renal deficiency confirm the dread suspicion. Incautious catheterization easily empties the bladder but the patient may die in a few days of renal suppression from too sudden release of chronic tension. When a doctor rings me up and triumphantly relates that he withdrew 4 to 5 pints, I shudder, and spend ensuing days in anxiety. Better for the patient is it that he be sent unrelieved to an institution and deliberate gradual depletion then started. Various continuous drip drains or intermittent withdrawal of about three ounces hourly from a spigoted catheter may be adopted, and the bladder level marked daily on the abdominal skin as a further guide. If the bladder is only recently distended, then a more rapid depletion or complete evacuation is appropriate. In occasional cases, natural micturition returns after repeated catheterizations, and evidently a few days of such aid allow resolution where recent swelling of the prostate is merely congestive. Urinary antiseptics, bland drinks and even intravenous glucose and saline drip infusions where renal function is shaky, are used pending recovery and further radical measures. If catheterization fails or is intolerable, the surgeon resorts to supra-pubic drainage after deliberate exposure of the bladder wall to avoid accidental violation of the peritoneum, and gradual depletion is used where that precaution is necessary. Local anæsthesia or nitrous oxide gas are advisable. Where heavy hæmaturia complicates the prostatic case and clotting clogs the catheter, a large supra-pubic drain (No. 34 Malecot) is the least that will allow evacuation, and I have had to resort to immediate (and successful) prostatectomy. Cardio-respiratory complications share with renal risks the main responsibility for the considerable mortality this type of acute retention carries with it.

5. Instrumental interference in the bladder, especially with large cystoscopes in nervous folk or men with prostatic tendency, sometimes induces acute retention, which may call for temporary catheter relief, or, if there is pus about, supra-pubic drainage may alone be adequate. The cause is apt to be a mixture of local and nervous factors in this class.

6. Inflammatory conditions, septic, venereal or tuberculous in the prostate and vesiculæ have already been mentioned and abscesses in the perineum may prevent egress of urine. Their incidence in earlier decades, shorter history and tendency to pyrexia will, in such cases, put into the doctor's mind some alter-

native to prostatic neoplasm, although the mimicry may be very deceptive.

Local. In the female

Among women the opposite, incontinence, is a common complaint, whereas retention, owing to its rarity, makes unusual demands on diagnostic ability.

Acute vulvo-vaginitis causes reflex inhibition of micturition occasionally in infants, while, if hysteria is responsible in older girls, the usual stigmata will present themselves and organic causes will be lacking. Very rarely congenital atresia, or less rarely, inflammation cause stricture and chronic distension of the bladder. Expulsion of urine may be almost or completely impeded. Anæsthesia is sometimes necessary before the urethra can be penetrated, while the malformation may only be curable through a supra-pubic cystotomy. The retroverted gravid uterus, calculus or, in later years, impacted fibroid or urethral cancer are causes that careful examination defines and the cure of which calls for no mention here.

NERVOUS CAUSES

There remains a large group of patients already ailing from nervous maladies who are prone to acute retention as a complication of nervous dysfunction. Hysteria has already been discussed.

(a) Post-operative retention. The numerous ruses of the nurse and drugs invoked to overcome this bear witness to its frequency and duration. A halting mechanism may respond to one or two injections of 1 c.c. of 'Doryl'. If local heat, a glycerine enema, or cautiously sitting the patient on the edge or out of bed where permissible fail, careful catheterization cannot usually be deferred longer than 20 hours. This form of retention derives further importance because it is apt to be insidious and masked by the pain which the doctor expects to meet from flatulent swelling of the bowels. This confusion of urinary and alimentary disorder sometimes puts the patient's life in jeopardy.

Reflex retention is prone to occur after operations about the groin and perineum. It is one of the chief and most serious risks in removal of the rectum owing to derangement of the pelvic plexuses. In the male, I tie in a No. 8 rubber catheter which is changed every third day, and the urethra is irrigated. Recovery ensues after a week or two. I know of few greater demands on a nurse's dexterity and devotion than avoiding contamination of the bladder during repeated catheterizations in the female. In these cases the tendency to infection is mitigated by an acidifying medicine with hexamine and natural function usually soon recovers.

(b) The retention associated with head and spinal injuries requires catheters until consciousness returns, but when the cord is crushed in fracture dislocation of the spine, the outlook is grave unless, after a few weeks, automatic action develops under the control of the pelvic plexuses.

(c) In patients suffering from chronic disorders of the nervous system the causal disease has often already declared itself by other symptoms, or diagnostic signs are detectable.

Tabetics are liable to this trouble, as are folk with sclerosis, myelitis and compression paraplegia. In these, the doctor is apt to be more concerned by finding gross distension of the bladder than is the patient to complain thereof. A catheter is unimpeded and instrumentation well borne, but the trouble recurs. Where by reason of an obvious prostatic enlargement in a patient with dubious nervous disorder, it is reasonable to hope that the retention is curable by prostatectomy, this operation may be sound treatment. This would only be done after precautionary examination of his C. S. F. by a pathologist, a physician's and neurologist's blessing. The alternative, unless automatic evacuation develops and keeps retention in abeyance, would be permanent supra-pubic drainage.

The Causation and Treatment of Conjunctivitis

By R. A. GREEVES, M.D., F.R.C.S.

(Abstracted from the *Practitioner*, Vol. CXL, May 1938, p. 559)

THE conjunctiva is one of the most delicate of the mucous membranes of the body in so far as sensitivity, response to irritation, and liability to infection are concerned. When any mucous membrane is irritated or inflamed an increased formation of mucus occurs in response, and the conjunctiva is no exception to this rule; on the contrary, the association of gummy discharge with conjunctival inflammation is so constant as to be a reliable and therefore valuable factor in differential diagnosis. The mucus-producing cells of the conjunctiva are known as goblet cells, but they differ from those of the intestine in that they are completely cast off with their contents into the conjunctival sac. Any one of the cells of the stratified epithelium of the conjunctiva can apparently become transformed into a goblet cell—indeed, microscopical sections of inflamed conjunctiva show that a large proportion of them have done so. The number of cells thus transformed varies directly with the severity of the inflammation; clinically the amount of the sticky discharge varies in the same manner.

In addition to the mucus, which is normally an important factor in the lubrication of the lids and globe, lachrymal secretion is poured into the conjunctival sac. An increase in this secretion also takes place under the influence of irritation and inflammation, hence watering of the eyes is a symptom of conjunctivitis. But while increased lachrymal secretion occurs in association with many other forms of ocular irritation, e.g., corneal ulcers or iritis, an excess of mucus is poured out as a response to conjunctival irritation only, hence its special value in diagnosis. In questioning a patient as to symptoms, it is best not to use the term 'discharge only' which is equally applicable to lachrymal and mucus secretion, but to qualify it with the terms 'watery' and 'sticky'. In mild cases of conjunctivitis when mucus discharge is scanty none of this discharge may be visible at the time of examination—or possibly only a small quantity in the neighbourhood of the caruncle. But it is always apt to collect during sleep, hence the patient suffering from even the mildest conjunctivitis will usually admit to the presence of some sticky secretion, either on the edges of the lids or in the corners of the eyes when waking in the morning. In more severe cases of course, the eyelids may be so glued together that the patient cannot open them until he has removed the semi-dried glutinous matter.

The conjunctiva, like other mucous membranes, consists of a surface epithelium and a supporting tissue. The structure of this epithelium varies in different parts—on the eyelids it is two-layered, but in the fornices and on the globe definitely stratified. This structural difference may have some bearing on the fact that certain parts of the conjunctiva are more affected than others by different kinds of infection. To give two examples—trachoma first attacks the retrolarsal fold of the upper lid, and in chronic staphylococcal infections the bulbar conjunctiva is not involved.

The subepithelial supporting tissue is extremely loose in the fornices and on the globe, and for this reason is capable of great distention by oedema (chemosis) in response to acute inflammation of the conjunctiva or of the eyelids. A familiar example of this is the ballooning of the conjunctiva which occurs in association with a virulent 'stye' on the eyelid.

In concerning conjunctivitis in general it must be remembered that the cornea may be affected by the same agents which give rise to the conjunctival disturbance.

TREATMENT OF INFECTIVE CONJUNCTIVITIS

As I have already pointed out, the conjunctiva is a particularly delicate mucous membrane. It will

therefore not tolerate any but relatively weak solutions of substances which are at all irritating, and as no one has yet succeeded in discovering antiseptics devoid of irritating properties, these can be applied to the conjunctiva only in dilute form. Indeed, the results of experiments on the effect of antiseptic drugs in strengths commonly used as eye lotions, on cultures of micro-organisms *in vitro*, have led laboratory workers to deny that drugs so dilute have any bactericidal effect and to maintain that washing out the conjunctival sac with a non-irritant such as normal saline would be equally, if not more, beneficial. But clinically this view is not borne out by results; on the contrary, the curative effect of appropriate antiseptic solutions is most striking.

In the treatment of the two commoner groups, catarrhal and mucopurulent conjunctivitis, a mercurial solution, such as hydrarg. perchloride 1 : 10,000, mercurochrome 1 per cent or hydrarg. oxycyanide 1 : 8,000 can be used. The hydrarg. oxycyanide is much less irritating than the perchloride and has not that great disadvantage which the use of mercurochrome entails, namely, the staining of the skin of the eyelids a bright red colour. The conjunctival sac should be washed out two, three, or four times a day with the solution according to the severity or chronicity of the case. The washing out must be thorough, but not too long continued, about half a minute at a time, and the most effective method is by means of an 'undine' but as this vessel must be manipulated by a second person and the method is a 'messy' one, it is not always possible for the patient to adopt it. The next best thing is an eye-bath of the usual pattern. In cases of catarrhal conjunctivitis of an 'angular' type (Morax-Axenfeld) zinc sulphate must be added to the solution— $\frac{1}{2}$ grain to the ounce is sufficiently strong. Even in this dilution the zinc sulphate has considerable irritant and astringent properties, but owing to the fact that the itching peculiar to this type of conjunctivitis is allayed by these particular properties, the solution is usually well tolerated. This (angular) is the only type of conjunctivitis in which the use of a zinc salt is beneficial—in the other types it merely irritates without doing any good. My reason for using the hydrarg. oxycyanide in solution in addition to the zinc sulphate is that a *Staphylococcus aureus* infection is usually present concurrently with that of the Morax-Axenfeld diplobacillus.

To relieve and prevent the matutinal stickiness of the eyelids an ointment of some kind should be inserted between them at night. Simple yellow vaseline or boracic ointment is effective, but in the 'angular' cases, and in chronic staphylococcal cases, especially when the glands and hair follicles of the lower lid have become infected, I prefer the following:—

R. Ichthyol	0.15 parts
Zinc oxide	2 "
Vaseline (yellow)	15 "

This should be rubbed on the lid margins besides being introduced between them. Any mercurial solution is an irritant, consequently the patient may not feel that his eyes are quite normal until two or three days have elapsed after its use has been discontinued. In the early stages of an attack of mucopurulent conjunctivitis an application of 1 per cent silver nitrate to the palpebral conjunctiva is of value, and indeed in my opinion considerably hastens the cure. A wool-mounted probe or glass rod is dipped into the solution and lightly brushed over the conjunctival surface of the everted lids. In severe cases this may with benefit be repeated daily for two or three days, but a single application is usually enough. The eye may previously be anesthetized with drops of 2 per cent cocaine hydrochloride. Also in cases of chronic conjunctivitis when the palpebral conjunctiva of the upper lids has become granular and rough, silver nitrate solution (1 or 2 per cent) should be applied to the everted lids in this way, at intervals of two or three days, until the conjunctiva has resumed its normal smooth appearance. A case of chronic conjunctivitis is occasionally seen conforming mainly to the catarrhal type, but resulting

from an initial, insufficiently treated mucopurulent attack, and really pneumococcal in origin. In this type of case 1 per cent optochin in the form of drops two or three times daily may be of great benefit; this treatment is, however, rather painful and for this reason can rarely be prolonged for more than a few days. I have found optochin useful in clearing up the residual conjunctivitis after an operation for removal of an infected lachrymal sac.

No mention has yet been made of the various preparations of silver for the treatment of conjunctivitis which are on the market. I have found them to be of singularly little benefit in the treatment of chronic catarrhal conjunctivitis. Argyrol or protargol drops may, however, be used in addition to the mercurial solution in the treatment of mucopurulent cases; one or other of these preparations may be dropped into the conjunctival sac after it has been washed out with the mercurial solution, and repeated at more frequent intervals. Argyrol is singularly unirritating and can therefore be used in strong solutions, but a 1 per cent solution of protargol, which is definitely an irritant, is sufficiently strong for frequent use. Incidentally the longer a solution of protargol is kept, especially if exposed to the light, the more irritating it becomes, and stale protargol, which has been kept for a long time among a chemist's stock of drugs, may be excessively so. Protargol, on the other hand, is probably more effective than argyrol; indeed it has been shown to possess definite bactericidal properties *in vitro*.

A preparation, of the use of which I entirely disapprove in the treatment of infective conjunctivitis, is the well-known ung. hydrarg. oxidi flav. (golden ointment). It is a strong irritant, and its mercury content is too insoluble to act as an antiseptic. For the endogenous varieties of conjunctivitis, however, in which the use of a stimulant is beneficial it is extremely useful. An ointment which may be valuable in cases of chronic staphylococcal conjunctivitis is the following:—

R Hydrarg. perchlor.	1/5 grain
Aq. dest.	q.s.
Adipis Janæ	20 grains
Paraff. liq.	240 minims
Paraff. mollis flav.	1 ounce

It is inserted between the lids at night, but its use should not be kept up for more than a week at a time, otherwise the effect is apt to become too irritating.

If for any reason it is thought necessary to prescribe a simple eye lotion, boracic acid solution or normal saline is as suitable as any of the much vaunted proprietary preparations. Of these two, normal saline is probably the safest, as certain persons show a definite idiosyncrasy to boracic acid; normal saline is also nearest in composition to the lachrymal secretion. But I do not approve of the regular use of eye lotions for normal eyes. The normal lachrymal secretion is quite adequate; also, it has been shown to possess antiseptic properties, and these are almost certainly destroyed by the use of drugs of any kind.

Infection of the Meibomian glands has been mentioned as a cause contributory to the persistence of a chronic conjunctivitis. When this is present I have found that the massaging of these glands with a glass rod on several occasions, at intervals of a few days, has contributed markedly to the cure of the conjunctivitis.

Chronic conjunctivitis may be secondary to an infection of the lachrymal sac; indeed in any case of obstinate chronic conjunctivitis the condition of the lachrymal sac or sacs should be explored. And this applies especially to infants; it is comparatively common to see babies with intractable conjunctivitis (monocular or binocular) and mucopurulent discharge, in whom the condition is entirely due to a sac infection and clears up completely when the latter has been attended to.

Conjunctivitis in infants, apart from gonococcal conjunctivitis, is most commonly of the mucopurulent type. The infant's conjunctiva is even more sensitive

to irritants than that of the adult, and especially so to mercurial solutions. Hydrarg. oxycyanide should not be used in a stronger solution than 1 : 10,000, and is usually effective if applied three times a day in the form of drops. If much sticky discharge is present, the eyes should be washed out with boracic or normal saline lotion before the drops are applied. After each application a small quantity of boracic ointment or vaseline should be introduced into the conjunctival sac. Argyrol 10 per cent, also applied as drops, is useful as an adjunct to treatment with the mercurial solution, and also as a substitute in cases which do not tolerate the mercurial solution well.

A mild conjunctivitis may occur soon after birth as the result of the use of silver nitrate drops for the prevention of ophthalmia neonatorum, especially when a strength of 2 per cent has been employed. This type of conjunctivitis is a response on the part of the conjunctiva to the chemical irritant and clears up quickly on simple treatment with normal saline or boracic lotion, and vaseline or boracic ointment.

Gonococcal conjunctivitis is so serious a disease that it must always receive expert treatment. Suffice it to say that the most essential factor in its treatment is frequent (in babies) and continuous (in adults) washing out of the conjunctival sac with non-irritating fluid, saline or boracic, in order to prevent, if possible, any prolonged contact between the infected discharge and the corneal surface. As the washing out has to be done so frequently, the use of an antiseptic is not advisable; it would inevitably cause too much irritation. In babies both eyes are usually affected from the start, but in adults the primary infection is monocular. In this latter case the normal eye must at once be hermetically sealed, with strapping and a watch glass (Bullar's shield) to prevent, if possible, any chance of its involvement.

Membranous (diphtheritic) conjunctivitis should be treated on the same lines as are other diphtheritic infections, namely, by subcutaneous injection of anti-toxin. The conjunctival sac should be washed out with simple lotions (e.g., boracic). These cases must, of course, be notified and sent to an isolation hospital.

With regard to the danger of spread of infection in cases of infective conjunctivitis, all varieties are potentially contagious. But the degree of contagiousness varies directly with the copiousness of the discharge, in other words, with the liability of such discharge to reach the contaminate the eyes of other people. Catarrhal conjunctivitis, with its scanty discharge, is but rarely communicated to others, whereas mucopurulent conjunctivitis is notorious as a 'spreader'—it runs through schools with great rapidity.

Peptic Ulcer

By JOHN D. COMRIE, M.A., B.Sc., M.D., F.R.C.P.E.
(From the *Prescriber*, Vol. XXXII, August 1938, p. 241)

THE old theory of Virchow that thrombosis occurs in small blood-vessels of the mucous membrane, with subsequent degeneration and digestion of the surrounding tissues, is probably applicable to some cases, especially in elderly persons in whom arteriosclerosis is present. As a basis for a neurogenic theory of causation, Cushing recorded three cases of cerebellar tumour in which, after apparently successful removal, death had occurred owing to the perforation of an acute peptic ulcer. He noted two other cases which had occurred after similar operations by other surgeons, and two cases after a tumour under the third ventricle. Schiff had already shown experimentally that pontine and medullary lesions were apt to be followed by erosions of the gastric mucous membrane, and Cushing, apart from such gross lesions of the nervous system as a neurogenic cause, is inclined to attribute the prevalence of peptic ulcers in human beings to the general strain and stress of life. Ryle pointed out that duodenal ulcer had doubled in frequency in the decade preceding 1932. He had found that the type of persons

who were preponderantly affected by this condition were restless energetic men with stomach of the steer-horn type and of the ages between thirty and fifty. He was inclined to attribute this increase to general nervous influences on the principle that 'a restless stomach accompanies a restless mind'. Davies later pointed out that emotional upsets were apt to be associated with increased acidity of the gastric juice. Experimental evidence was produced by Matthews and Dragstedt in support of the view that the chemical action of pepsin with hydrochloric acid could by itself produce a typical chronic progressive ulcer in the stomach, duodenum, or lower part of the alimentary canal without any other predisposing cause. Dragstedt went so far as to attribute the origin of the ulcer directly to the amount of hydrochloric acid in the gastric juice, and suggested that 'acid ulcer' would be a more accurate term for the condition than peptic ulcer.

Another important factor in causation has been pointed out by Archer and Graham who suggest that deprivation of vitamin C, which in animal experiments has been found associated with gastric ulcer, is in many cases the main reason for the continuance of a peptic ulcer. They suggest further that a strict diet for peptic ulcer was often lacking in the necessary ascorbic acid, and that recovery is expedited by the administration of two ounces of orange juice daily, or of one dose of one gramme of ascorbic acid followed by administration of thirty-six milligrams of this substance daily thereafter.

Various new methods of treatment or modifications of older methods have also been tried recently. A form of pepsin therapy for gastric and duodenal ulcer was proposed by Glaesner. He recorded 600 cases which had been treated by a course of thirty subcutaneous injections of pepsin sterilized by passage through a porcelain filter, and he claimed recovery for 60 per cent of patients treated in this manner. The method, however, does not seem to have a physiological basis and has not met with general approbation. A method of treatment by application of gastric mucus to the stomach was recommended by Fogelson. This was based on the principle that 100 c.cm. of mucus will inhibit *in vitro* 40 c.cm. of gastric juice. A prolonged course of prepared gastric mucus was administered by ambulatory treatment to 555 patients who at the same time were kept on a bland diet and whose cases were followed for varying periods from six months to three years. Fogelson claimed that in 70 per cent of these cases all the symptoms of peptic ulcer were controlled and that relief was obtained in another 23 per cent. Owing to difficulties in obtaining gastric mucus and repugnance on the part of patients this method has not been adopted by other observers, although Fogelson in a later paper still recommended it and found it had produced benefit in 88 per cent of his cases, having the effect of inhibiting excessive gastric secretion and motor activity.

Considerable discussion has taken place, regarding the comparative value of medical and surgical procedures in the treatment of peptic ulcers. Emery and Monroe in a review of 1,435 cases which they had treated, came to the conclusion that the ultimate results of medical and of surgical treatment were much the same, with recovery in about 32 per cent of cases. They found that peptic ulcer was associated with hæmorrhage as one of its symptoms in over 34 per cent of their cases, and they concluded that a case accompanied by hæmorrhage was entirely a medical problem since the mortality was greater among patients upon whom an operation was performed than among those treated by medical procedures. They obtained the best results by strict adherence to the Sippy regimen of diet. Tidy from a large collection of statistics also came to the conclusion that the same late results followed medical and surgical treatment. The operative mortality, however, lay between 10 and 20 per cent and when gastro-enterostomy was performed, a gastro-jejunal ulcer was liable to form in at least 10 per cent of cases.

Much interest has centered upon the treatment of gastro-duodenal ulcer by injections of histidine monochloride. Weiss and Aron, as the result of animal experiments, concluded that under certain conditions duodenal ulcers developed for want of the duodenal contents containing histidine and other amino-acids which were present in the food but could not be developed by the body. They succeeded in producing healing of these experimental ulcers by injections of histidine and certain of these other amino-acids, and they later applied this treatment with apparent success to twelve patients who were suffering from duodenal ulcer. Bulmer recorded 52 cases with 58 per cent of recovery as shown by disappearance of clinical symptoms confirmed by x-ray examination, and 23 per cent of failure, while numerous other observers in Britain and America have recorded smaller series of cases treated with histidine under various proprietary names (larostidin, stillidin, etc.). Sandweiss made a systematic study of this form of treatment in the following way. He treated 67 patients, of whom the great majority had had symptoms of peptic ulcer for five years or longer, giving them the option of being treated by twenty-four injections of histidine or by administration of diet and alkalis according to the Sippy regimen. The patients who remained unimproved after some four weeks were then treated by the other method, those who had not recovered under histidine injections being put on diet and alkalis, and those who had not recovered under diet and alkalis receiving a course of histidine injections. Thus in all 40 patients were treated with histidine and 53 with diet and alkalis. The results were practically the same in the two classes, but he noted the fact that there was a recurrence of symptoms at a later date in 85 per cent of the patients treated with histidine. As a control to the histidine injections, he treated another series of patients by injections of distilled water, and found that almost the same percentage became free from symptoms with the latter treatment. He concluded therefore that the treatment by diet and alkalis was the most satisfactory, but that as an addition injections of histidine might be useful for what he called 'extra artillery'.

An elaborate series of observations has been carried out by Dr. David Wylie in the wards of the Royal Infirmary, Edinburgh, under the writer's charge. He examined a long series of patients with normal acidity and suffering from hyperchlorhydria with or without gastric ulcer, leaving a small gastric tube in the stomach for twelve hours and taking half-hourly readings of the gastric acidity during this period. He found that in normal degrees of 'free' acidity, hourly administration of three ounces of milk was sufficient to maintain adequate neutralization of the gastric contents. In cases of hyperchlorhydria, the neutralizing action of magnesium trisilicate, calcium carbonate, magnesium oxide, aluminium hydroxide, and tribasic magnesium phosphate was also investigated. Magnesium trisilicate and aluminium hydroxide proved to be the most efficient remedies in maintaining persistent alkalinity, but the original powders recommended by Sippy of calcium carbonate and magnesia combined with sodium bicarbonate were little less efficient. Two-hourly feeds of milk (5 to 6 ounces) and 60 grains of either aluminium hydroxide or of magnesium trisilicate half an hour after the feeds given during the day would almost completely and at all events adequately neutralize the free acid.

The treatment of hæmatemesis from a peptic ulcer has attracted a good deal of attention lately and has involved a discussion of comparative advantages of surgical and of medical treatment. Means expresses the opinion that when a patient has developed a gastric ulcer, he should be treated medically for the rest of his life. With regard to surgery, absolute indications for an operation are the occurrence of perforation, symptoms of obstruction, and a laparotomy to exclude the presence of cancer, but in regard to hæmorrhage, operations should be limited to patients over the age of fifty in whom arteriosclerosis is present and the

hemorrhage may be expected to be recurrent. Finsterer is one of the strongest advocates for a surgical treatment and claims that in a large number of cases he obtained good results in resection of a part of the stomach for hemorrhage, provided that the operation was carried out within forty-eight hours of the occurrence of the hemorrhage, since he admits that the mortality was about 30 per cent at later periods. Still recording 80 cases of simple ulcer in which subtotal gastrectomy had been carried out, met an immediate mortality in 5 per cent of the cases and out of 57 cases whose subsequent history it was possible to trace, 90 per cent were found to have remained in a satisfactory state. Goldman recording the results following large resections for peptic ulcer in 890 patients treated in the Hospital for this condition, found that death occurred much more frequently in cases between the ages of forty and seventy years than at earlier periods of life, and that the mortality rose when hemorrhages were repeated. He concluded, therefore, that surgical intervention should be considered in elderly persons in whom a large hemorrhage had occurred, but that at earlier ages the most effective means of treatment were the administration of morphine and blood transfusion, food being withheld till the hemorrhage ceased. Hurst and Ryle discussing the whole question of hemorrhage in relation to gastric and duodenal ulcer, found that the number of cases of peptic ulcer in which hemorrhage occurred was larger than is generally supposed, this complication occurring in 31 per cent of cases of peptic ulcer, and in 45 per cent of cases in which gastrojejunostomy had been carried out. They concluded therefore that operation was likely to increase the mortality. They considered further that the mortality in cases of hæmatemesis had been grossly exaggerated, for this complication occurred in not more than about 1.5 per cent of cases in general practice, and in about 4.8 per cent among cases admitted to hospital on account presumably of severer hemorrhage. The mortality which occurred after any operation performed on cases of hemorrhage was therefore greater than that found in cases of hemorrhage generally, and moreover the fact had to be remembered that hemorrhage often recurred either from the original site or from the site of anastomosis after an operation had been performed. They considered that the best line of treatment included rest in bed, starvation, and the administration of morphine, while transfusion was occasionally required but not in every case. They did not agree that feeding patients suffering from hemorrhage from the commencement, a procedure recently recommended by several authorities, presented any advantage over starvation in preventing death.

In the treatment of hæmatemesis, withholding of food at the commencement and nutrition by means of glucose, together with administration of morphine and, if necessary, transfusion of blood, is the treatment adopted by the majority of hospital physicians. At a later stage, after the hæmatemesis has ceased the most frequently adopted method of feeding and of checking excessive secretion of hydrochloric acid is by the regimen introduced by Sippy. This consists of administration of milk and cream in small quantities, from three to six ounces at a time every hour or every two hours, with alkaline powders in the intervals, and the gradual addition of eggs, cornflour, puddings, and lighter forms of protein food as the case progresses. Meulengracht recommended that patients suffering from hæmatemesis should be treated from the beginning by a feeding process which he alleged counteracted the shock and anæmia induced by the hemorrhage and led to more rapid recovery. His method consisted in the administration of a purée diet together with an alkaline mixture containing sodium bicarbonate, magnesium carbonate, and extract of hyoseyamus. The diet began in the morning at 6 a.m. with tea, and white bread and butter; at 9 a.m. oatmeal porridge with milk, and bread and butter; at 1 p.m. dinner, including such articles as meat balls, omelette, fish balls, mashed potatoes, vegetable purées, stewed fruit, gruel, and

pudding of rice or tapioca; at 3 p.m. cocoa; and at 6 p.m. white bread and butter, sliced meats, cheese, and tea. He recorded 251 cases in which there had been severe hemorrhage probably due to ulcer, with three deaths, or approximately 2 per cent, which he held was lower than the mortality that followed starvation treatment. He also said that on such a diet melena had continued on the average for 10.2 days only, and that the patients had made a more rapid recovery than they would have done on a starvation treatment. This view however is negated by the observers already quoted.

Woldman recommends a method of carrying out the treatment for neutralization of excessive acidity more thoroughly than by the usual method of administering alkalis hourly or half-hourly. He treated 21 cases by a drip method through a stomach-tube introduced as far as the cardiac end of the stomach, and left in place; through this colloidal aluminium hydroxide, 5 per cent in 0.6 per cent sodium chloride solution was allowed to drip at the rate of ten drops per minute for ten days into the stomach. For food the patients received two ounces of milk and cream every two hours for the first day, and later such semi-fluid foods as cream soups, cereal foods, rice and tapioca puddings, custard, etc. Complete recovery resulted in all his cases.

Summary.—There appears to be general agreement at the present time that the chief factor in the development of most cases of peptic ulcer is the action of hydrochloric acid in excess of digestive requirements, and that nervous states such as over-work and worry influence this. Vascular conditions such as arteriosclerosis play a part, especially in the ulcers of elderly people. Most authorities agree that medical treatment should be pursued in the great majority of cases, this treatment consisting in the administration of bland, semi-fluid diet at frequent intervals, with the addition of alkalis to neutralize the acid. Various forms of alkalis and absorbents have been introduced.

In cases accompanied by severe hemorrhage, most authorities favour temporary reduction of food given by the stomach, administration of morphine, and in occasional cases transfusion of blood, while surgical measures should be restricted to special cases.

Sulphanilamide in the Treatment of Genito-urinary Infections

By ANSON L. CLARK, M.D.

and

D. W. BRANHAM, M.D.

(Abstracted from the *Southern Medical Journal*, Vol. XXXI, April 1938, p. 387)

APPROXIMATELY six months ago the drug sulphanilamide was advanced as a remedy useful in the treatment of various infectious conditions of the genito-urinary tract. In that period of time a rather extensive clinical trial has been given to the substance, making it possible now to evaluate to some extent its therapeutic usefulness and also its limitations.

The reception given to every new discovery in the field of medicine has been ingeniously reduced to a graph by Edwin Davis, who points out that new medications and procedures of definite worth invariably follow a set path of acceptance in the minds of the medical profession. This course of evaluation begins with general indifference, which presently gives place to over-enthusiastic approval, sometimes commercially inspired by drug houses selling the preparation, or fostered by newspaper publicity; next, accidents occur, and pessimism supervenes, until finally, after a seesaw between hopes and fears, an awakening to the true therapeutic value of the drug or preparation arrives, and the substance reaches stability at its proper level of acceptance. This is running true to this form.

Following the work of the German chemists, Mietzsch and Klarer, on azo compounds, which resulted in the

discovery of substances with far greater action on bacteria than any azo compounds previously measured, Doinagk observed an interesting activity on the part of certain of these compounds containing sulphonamide in the streptococcal sepsis of mice. Next came the discovery that the azo radical could be eliminated without impairing the antistreptococcal action. From this as a starting point came 'prontylin', which is para-aminobenzene sulphonamide, first used therapeutically in Germany under the name of 'streptozon' and later as sulphanilamide. Curiously enough the new compound displayed almost no disinfectant action *in vitro* and it had no effect of any kind upon healthy mice, but its action upon certain strains of streptococci seemed specific. Against the staphylococcus also it was strongly bactericidal, while the effect upon the pneumococcus was to inhibit its growth.

The first American report was made by Long and Bliss early in 1937, on the basis of 70 cases treated, with four deaths, only one of which, however, could fairly be attributed to failure of the treatment. Shortly afterwards, Helmholz reported that the urine of patients to whom sulphanilamide has been administered develops definite bactericidal properties against such organisms as commonly flourish within the urinary tract. Among these, he found the staphylococcus to be the most easily affected, while at the other end of the range stands *Streptococcus faecalis*, which continues to grow luxuriantly in urine that will completely inhibit the growth of the Gram-negative group in twenty-four hours. He also observed that the new drug is more effective in alkaline than in acid urine, and that the urine tends to be alkaline after its administration. He expressed the view that its ease of administration, its action in alkaline urine and its successful use in clearing up infections resistant to mandelic acid made it a urinary antiseptic of great value.

Then Dees and Colston, working at Johns Hopkins University Hospital, recorded that sulphanilamide has a definite bactericidal effect on the gonococcus. Since it is difficult to infect animals with this organism, they tried the clinical application of the new drug in 19 cases of gonococcal infection, finding that in nearly all instances the discharge disappeared within 1 to 4 days after treatment was instituted, and most of the smears were negative for gonococci in 2 to 5 days.

Because these authorities have been widely quoted we wish to emphasize at this time that while negative smears may be obtained in 2 to 5 days it does not mean that the infection has been eliminated. In numerous instances where a short course of the drug is given the organism will again be found in the urethra within 10 to 12 days after the medication is stopped. Careful observation and frequent tests of cure are important when sulphanilamide is used in treating gonorrhœa.

Dees and Colston were also impressed with the fact that the infection had not extended from the anterior to the posterior urethra, thereby minimizing possible complicating factors, and in this we heartily concur. Since February 1937, we have been using sulphanilamide at our clinic in genito-urinary infections of the most varied kind, and it is our opinion that its therapeutic value in these conditions when properly administered is important.

NON-SPECIFIC INFECTION OF THE URINARY TRACT

Pyelitis.—In our experience acute upper urinary tract infections respond quite satisfactorily to the medication, except in cases of stone or stasis, where of course the causative factor must be removed before infection can yield to treatment by chemotherapy. In other conditions we feel that the course of the infection is materially shortened clinically and the symptoms are ameliorated. This is evidenced by a more rapid fall in temperature and by clearing of the urine. Where sulphanilamide cannot be administered by mouth because of gastric intolerance, we have successfully given it in 0.8 per cent solution by hypodermoclysis. Acute bacillary infections of the

kidney have responded more satisfactorily than the coccal infections.

Cystitis.—Administration of the drug in instances where bladder infections occur following surgical procedures on the bladder neck has not been particularly successful, especially in the first few post-operative weeks. When, however, sufficient time has elapsed for all necrotic material to be eliminated from the operative area, sulphanilamide is an aid in relieving the residual infection.

Acute trigonal cystitis, seen often in women, and usually of bacillary origin, is uniformly aided by the drug. Rarely will acute bladder symptoms persist more than twenty-four hours after its administration. Nevertheless, it is advisable to continue therapy until the offending organism has been completely eradicated.

Non-specific prostatitis.—Results obtained in non-specific infection of the prostate where the gonococcus is not present have not been altogether satisfactory. Although administration of sulphanilamide will produce a decrease in the extent of the infection, revealed by microscopic examination of the expressed secretion, recurrences are frequent when the drug is discontinued. Neither persistence in the medication nor the size of the dose seems to alter the situation materially. Twenty to thirty grains of the drug will produce as much benefit as a more massive dosage. For the desired results more dependence must be placed on regular prostatic massage over a sufficient period of time.

In our experience the administration of sulphanilamide in small doses (30 grains daily) for a few days before operative procedures are performed on the urinary tract reduces the intensity of possible post-operative reactions. In cystoscopic manipulation for urethral calculi, fulguration of urethral conditions, or prostatic resections it is evident that the drug by inhibiting bacterial growth shortens the convalescent period.

GONOCOCCUS INFECTION

When one realizes that this medication is not specific for gonococcal infections it may be said that our results obtained in the treatment of gonorrhœa have been quite satisfactory. Over 300 such patients have been treated with the preparation, the majority of these being in private practice. Sulphanilamide therapy in dispensary patients is accompanied by difficulties because of an inability to observe the progress in these patients until a definite cure has been accomplished. Invariably this class of patients fails to return to the clinic when gross evidence of their infection disappears. A false sense of security is engendered in them through the erroneous belief that they have been cured and as a result they will return to normal sexual activities, thereby causing a wider spread of the disease. As a point in the public health control of gonorrhœa we feel that this phase of sulphanilamide therapy has not been sufficiently emphasized.

In acute anterior urethritis of gonococcal origin we have found the drug most useful in preventing posterior complications and extension. It must be remembered, however, that the ultimate cure is brought about by the patient's own immunological response to the infecting organism. If the drug so inhibits the growth of the gonococcus that this immunological reaction is lessened or slowed down, the complete cure may be hindered instead of hastened. We must also bear in mind that by lessening the discharge sulphanilamide eliminates evidence of the disease, allowing the patients, and sometimes even the physicians, to think that a cure has been accomplished when this is not the case. In this way the possible spread of the disease may actually be encouraged.

DOSAGE OF SULPHANILAMIDE

It has been our aim to keep the dosage of the drug within reasonable bounds. We do not share the view of Dees and Colston, of Long and Bliss and certain other authors that it is important to administer a

large amount (80 grains) during the first twenty-four hours of treatment, and then lessen the dose by a third or a half on the third and fourth days. It has not been necessary to give more than 60 grains daily (divided into 4 doses) for two days; we cut this down to 40 grains for the next five days, and to 30 grains during the second week. If renal function is poor, and there is evidence of possible lack of tolerance, the initial dose is smaller than 60 grains. A dosage of 80 grains a day for two days, which was first advised for streptococcal infections, is in our opinion unnecessarily large for the average patient who is ambulant and attempting to work and will invite complications.

Experience has shown that no standard dose can be established since the amount must vary with the individual patient. In younger patients the kidneys will excrete the drug more rapidly, and will thus lessen the blood level of the drug. On the other hand, if the substance is excreted slowly by the kidneys, the blood level will be raised, even though the dosage of the drug is small. This possibility of impaired renal function must always be taken into consideration.

Some urologists, as Cook and Buchtel, begin not with large doses that are to be decreased, but in just the opposite way: Walther, for example, writes that he considers it much safer to begin with definitely small doses (18 grains daily = 1.2 gramme) for two days, and then to increase these if they are well tolerated. Beginning then with the fourth day, he gradually increases the amount until he reaches 80 grains daily.

Rarely is the drug given for more than two weeks, for it is found that the optimal results are obtained within this length of time. The first ten days are the golden period of therapeutics so far as sulphanilamide is concerned. Doubtless the offending organisms by that time have built a tolerance toward the medication that hinders a complete cure. Furthermore, we believe on general principles that continuous medication with one and the same preparation over long periods of time is fraught with danger, because of the possible cumulative effect. With sulphanilamide this danger would seem especially great, due to its possible depressing effect upon the hematopoietic system.

COMPLICATIONS

Serious complications encountered in our experience with the drug have been surprisingly few. We believe that our conservatism in dosage, together with frequent observation of the patient, contributes to this end. We are of the opinion that the drug is of such importance as a therapeutic agent and holds such potentiality for development of serious complications if carelessly administered, that no patient should be entrusted with it for any length of time without close medical observation. No need has been felt for daily blood counts to determine whether anaemia is present, since the general appearance and state of well-being of the patient have in all cases given a sufficient hint to the physician. Whenever any undue difficulty is encountered, cessation of medication has uniformly resulted in rapid improvement. As an added safeguard, the drug is dispensed from the office only in such quantities that no more than two or three days' supply is held by the patient.

Among specific complications met with, skin manifestations have constituted the majority. In the few dermatoses that have been produced, it has been possible to discontinue the drug for a few days and return to it at a later date when the eruption has disappeared; and in no cases has there been a recurrence, although this has been frequently reported by other writers. Practically all the patients complain of dizziness and lassitude, together with loss of appetite. Unless these symptoms are unusually severe, they are ignored, as we feel they indicate satisfactory systemic absorption. By the second week these manifestations usually diminish in intensity. In this series no serious instances of anaemia have developed, as some authors have reported. One patient developed an optic neuritis while under treatment, which may have been due to

the drug. Fortunately this condition improved upon withdrawal of the drug.

Sulphamides, such as methæmoglobinæmia, again, which a number of authors have uttered a warning, have not been observed among our patients. Caution is observed that no magnesium sulphate or other saline cathartics are taken with the sulphanilamide, nor do we allow any other adjuvant medication except sodium bicarbonate.

Before leaving the subject of complications, it seems that reference should be made to the very recent reports of 73 deaths from the use of a so-called 'elixir of sulphanilamide' that has been sold without its producers having tested its properties. Investigation has brought to light the fact that these deaths were probably due to the presence of large amounts of diethylene glycol, and not to the sulphanilamide ingredient. The chief symptom in these fatal cases was anuria, which has never been observed following the ingestion of sulphanilamide, but which has now been shown by animal experimentation in the laboratories of the American Medical Association to follow the use of diethylene glycol. The latter substance is not a pharmaceutical remedy, but a toxic preparation used in the mechanical arts, entirely unsuitable for human consumption.

RESULTS IN TREATMENT OF GONORRHOEA

An evaluation of the results obtained with this type of medication in gonorrhœa is still somewhat difficult. We feel that the benefit accruing from shortening the length of time of active symptoms and the lessened number of complications as compared with that of the past has shown the drug to be a very valuable adjunct in treatment of gonorrhœa. In our hands, however, it has not replaced the more accepted methods of treatment for this disease.

As the cure of gonorrhœa is based on a personally developed immunologic reaction between host and organism, and as stimulating local therapy in conjunction with proper hygienic control of the patient is a potent factor in promoting this immunity, we have been loth to dispense with these time-honoured methods of treatment. For these reasons, patients are given the same therapeutic routine as formerly, and sufficient time of observation is taken before they are discharged as cured.

Briefly our records show: ten per cent of the patients with an acute anterior gonococcal urethritis treated with sulphanilamide will apparently be radically cured within forty-eight hours. By a radical cure we mean that continuous observation of these individuals over a period of weeks combined with repeated 'tests of cure' produced no evidence of the disease. Seventy-five per cent of patients will be improved by administration of the drug as shown by diminution in the amount of urethral discharge, with recovery completed at the end of four to six weeks. Fifteen per cent of patients seem to obtain no therapeutic results whatever with the medication. They continue to have signs and symptoms of infection for long periods of time, with or without complications in the form of acute and chronic prostatitis. However, serious complications have been markedly reduced and those that do occur may be explained as due to a lack of normal resistance to the disease or on a basis of poor behaviour. The acute symptoms of posterior urethritis are rapidly relieved by the drug. The benefit from sulphanilamide in acute epididymitis has been less spectacular. It apparently does not materially shorten the course or intensity of this complication. In our experience, acute iridocyclitis and arthritis have also been disappointing in response to this treatment.

The results in chronic gonococcal infections, occurring in those who have not received the drug previously, have been extremely satisfactory. Chronic prostatitis of gonococcal origin is apparently rapidly improved by the medication, as determined by examination of the expressed prostatic secretion and appearance of the

urine. If, however, non-specific infection be present as a complicating factor, the end results are not satisfactory. As these non-specific infections of the prostate gland constitute a large proportion of the infectious pathologic conditions of this gland, and as it is practically impossible to differentiate these from gonococcal infections, the difficulty is obvious in evaluating this phase of therapeutic benefit.

Peri-urethral infection of gonococcal origin has been less favourably influenced by the drug than prostatitis. In such cases we find that infection tends to persist, and more dependence must be placed on local measures. Possibly the concentration of the drug when it is excreted in the prostate gland is much higher than

that which obtains in the glandular structure of the anterior urethra.

In conclusion, sulphanilamide is a valuable therapeutic measure for use in genito-urinary infections. When it is properly employed, with strict attention to its capacity for producing harm and a clear knowledge of its limitations, it is a worthy addition to our medicinal armamentarium. At times the results produced in combating gonorrhoea are spectacular, but it frequently masks the signs and symptoms without eradicating the infection completely. Provided the physician is aware of this fact, it will prove to be a drug of tremendous merit in diminishing the clinical intensity of the disease.

Reviews

THE BRITISH ENCYCLOPÆDIA OF MEDICAL PRACTICE.—Under the General Editorship of Sir Humphry Rolleston, Bt., G.C.V.O., K.C.B., M.D., D.Sc., D.C.L., LL.D. 1938. Butterworth and Company, Limited, London. (To be completed in 11 volumes.) Sold in complete sets only. Cash price, Rs. 25 per volume. Also available on the instalment system at Rs. 10 per month. Price, Rs. 26-8 per volume. Only available from Messrs. Butterworth and Company (India), Limited, Calcutta. Volume VI. Pp. xx plus 602 plus 48

The range of this volume is from 'gonorrhoea to hydrotherapy'; the picture that this conjures up in the reviewer's mind is of an elderly man being wheeled round Harrogate in a bath chair. This is not the only volume in which the range is suggestive of a natural sequence of events and one might almost accuse the editor of chopping off the volumes at appropriate places, e.g., 'abdominal pain to appendicitis' (vol. 1), and 'diarrhoea to endoscopy of the rectum' (vol. 4), were it not impossible to suspect Sir Humphry of such levity, more appropriate to the idle fancies of a dilettante reviewer.

The first chapter is by Colonel Harrison, whose name one associates with some of the best work on this important but very difficult subject, gonorrhoea. It is still one of the most difficult of the non-fatal diseases to treat, and, though much progress has been made during the years since the last war, nothing really dramatic in the way of a specific has been found to help the physician, and the 'management' of the case is still the most important side of treatment. It is possible that a specific may be found in the sulphanilamide group of drugs, but when this chapter was written few of these had been tried and even now no finality has been reached. After a general introduction, the subject is dealt with under three main headings, gonorrhoea in males, in adult females, and in female children (vulvo-vaginitis).

Another venereal disease that is included in this volume is granuloma venereum which is described by Dr. R. V. Rajam; his contribution is based mainly on experience that he has reported from time to time in this journal. This chapter is followed by one on another disease very prevalent in India, guinea-worm infection; Colonel Liston who contributed this chapter made a special study of this subject when he was in India, and, though it is fifteen years or more since he retired, he has still maintained his interest in the subject.

Hydatid disease can claim a world-wide distribution, but it appears to have attracted far more attention in Australia than anywhere else in the world and it is therefore appropriate that this chapter should be contributed by the professor of surgery at Sydney University, Harold R. Dew, whose name is well known in connection with this disease.

A large section of this volume, nearly two hundred pages, is devoted to heart disease; the subject has been divided up into nine sections, congenital diseases, rheumatic heart diseases in children, pericardium diseases, endocarditis, malignant and non-malignant, mitral valve diseases, aortic valve diseases, right side diseases, and heart failure, and each section is contributed by a different writer, except that Dr. A. G. Gibson has written two sections. There is a certain amount of overlapping, but skilful editing has reduced this to a minimum.

The section on Hodgkin's Disease is written by a bacteriologist, Dr. M. H. Gordon, and a physician, Dr. A. E. Gow, with the editor acting as referee, so that this short chapter of only 12 pages of text has three names at its head. However painful was its birth—and it must have been a difficult labour to require three doctors—the chapter is a clear and concise presentation of the subject, in which present work on elementary bodies is not overstressed, though these have added a welcome relief, in the way of a hopeful note, to the otherwise distressing negativeness of the section on treatment of this fatal disease.

The chapter on heat stroke and heat exhaustion is written by Dr. Frank Marsh who is working with the Anglo-Iranian Oil Company at Abadan. A good account of the aetiology, physiology, pathology, symptomatology, treatment and prophylaxis of this condition is given by one who has obviously had considerable first-hand experience of morbid states due directly to excessive heat. There are few places in the world better than the Persian gulf for studying these conditions.

The same uniformly high standard of teaching and writing is maintained in all the chapters of this volume.

A TEXTBOOK OF HISTOLOGY: FUNCTIONAL SIGNIFICANCE OF CELLS AND INTERCELLULAR SUBSTANCES.—By E. B. Cowdry. Second Edition. 1938. Henry Kimpton, London. Pp. 600. Illustrated. Price, 31s. 6d.

It is very embarrassing for a reviewer, when he has just expressed the opinion that one book is the best book on the subject available at present, to receive another, which, if it is not better as a whole, has some sections that he considers quite definitely superior to the corresponding ones in the first. As it is better to avoid comparisons the reviewer will compromise by saying that, whilst he is prepared to stand by his original decision as to the suitability of the other book for the medical student, the physician and research worker will find the present book as useful; they should, in fact, be in a position to consult both.

The present edition is a considerably enlarged one; the book has been very extensively rearranged and about a hundred pages added. An introduction that did not appear in the first edition has been written for this one; it commences with an historical outline,

defines histology, and describes the organization of the body and the individual cell; an orthodox diagram showing cell division is given but there is also an interesting one contrasting the sizes of cells, from the filtrable of 0.02μ to the nerve cell fibre of $1,000,000\mu$; it is altogether a very suitable introductory chapter.

The chapters on the different blood cells have been revised very thoroughly and one on the formation and destruction of blood cells added. These are all good chapters, but perhaps one of the best is on the spleen. In no book have we seen the functional mechanism of the spleen explained so clearly.

The book is no mere compilation; the individuality of the author is reflected from every page. On the other hand dogmatic statement on any subject in which there is a possibility of division of opinion is always avoided; in fact, in the case of some of the most acutely controversial subjects, the author introduces the protagonists and then steps out of the ring, not as the judge but as a spectator, and often a mildly amused spectator.

The first edition of this book was a good one, but the second is very much better. The illustrations, both the diagrams and the photomicrographs, which are numerous, are relevant and clear; the former will give the student who is just commencing his studies a clearer conception of the subject than would many pages of description. For this and many other reasons we can recommend the book strongly to teachers in medical schools and colleges, as well as to physicians and research workers.

THE FUNCTIONS OF HUMAN VOLUNTARY MUSCLES.—By Norman D. Royle, M.D., Ch.M., F.R.A.C.S. 1938. Angus and Robertson, Limited, Sydney and London. Pp. 42. Illustrated. Price, 3s. 6d.

THIS little volume is a collection of lectures which the author delivered some years ago in the department of anatomy of the University of Sydney. There are four chapters dealing with different aspects of the functions of human voluntary muscles. Muscle tone has been described from two aspects. Firstly, the pre-spinal or extensor tone, affecting the anti-gravity muscles, is described as proprioceptive in origin but as absent in resting muscle. Secondly, spinal, or plastic tone, is said to appear with the onset of active contraction. Muscle tone is, therefore, regarded as 'a proprioceptive reflex action subserving active movements by taking up slack in muscle'. Both mechanisms are subserved, in the author's opinion, by the sympathetic nervous system which controls only blood vessels.

This view of muscle tone may not find general acceptance, but we agree with Professor Burkitt, who writes an informative introduction, that in this book the student and the clinical observer will find much that is worthy of attention and, indeed, much that is new.

P. N. R.

EVERYDAY SURGERY.—By L. Rogers, M.Sc., F.R.C.S.E., F.R.A.C.S., F.A.C.S., and A. L. d'Abreu, M.B., Ch.M., F.R.C.S. 1938. Edward Arnold and Company, London. Pp. xii plus 280, with 160 illustrations. Price, 12s. 6d.

THIS handy book is a daring effort to present in a concise form what may be regarded as the best in modern surgical practice of an everyday, as opposed to unusual or special, character. In an appropriate introduction Professor Grey Turner says that the purpose of this book is to 'smooth away difficulties and to focus attention on essentials' and that it is 'to be looked upon as a guide in emergency or as a remembrancer in times of stress and trouble'.

Consisting of twenty-four chapters, it adequately covers the whole of general surgery, but it must not for this reason be presumed to belong to the same class as the so-called 'aids' which only stimulate cramming. Special branches of surgery, such as ophthalmology,

gynaecology and oto-rhino-laryngology are naturally not included in this survey. It is a book which can be strongly recommended to the surgical dresser and even to the general practitioner. The printing, get-up, and illustrations are all praiseworthy.

P. N. R.

MINOR MEDICAL OPERATIONS: FOR SENIOR MEDICAL STUDENTS AND RECENTLY QUALIFIED PRACTITIONERS.—By K. Harris, M.A., M.D. (Cantab.), F.R.C.P. (Lond.), and E. Harris, M.B., B.S. (Lond.), D.P.H. (Eng.). 1938. H. K. Lewis and Company, Limited, London. Pp. x plus 198, with 41 illustrations. Price, 7s. 6d.

IN this book the authors have described the common practical procedures that have to be adopted in medical practice. The book is divided into two parts: the first part consists of sections dealing with the procedures and minor operative measures, such as paracentesis of the pleura, pericardium or peritoneum, artificial pneumothorax, venesection, blood transfusion, mechanical drainage of oedema, and lumbar and cisternal punctures, that are needed for the investigation and treatment of the diseases of the various systems, besides the methods of giving injections, administration of saline by different routes and of doing the various skin tests; the second part deals with the various nursing procedures and medical measures, such as the administration of oxygen and the use of the steam tent, and with the preparation of some common invalid diets, upon which the doctor may be expected to advise.

The sections are well written with an eye to detail, and the descriptions of the various methods are adequate. The instruments and apparatus described are those that are most commonly employed and are relatively simple to use. No attempt has been made, and rightly, to describe all the different methods and apparatuses that may be used in a medical operation.

Inclusion of descriptions of methods of making thin and thick blood smears, and of puncture of the spleen, liver, lymph glands and sternum, that are of so much use in diagnosis, would have enhanced the value of this book to medical practitioners in the tropics. Regarding the alcohol test meal, the meal that is more commonly used is 100 c.cm. of 7 per cent alcohol and not 50 c.cm., and the amount of histamine that is quite sufficient is 0.5 mgm.; higher doses may give rise to unpleasant symptoms. Regarding the administration of saline subcutaneously, the outer side of the thigh is regarded as the site of choice in the bigger hospitals of this country, in preference to infra-mammary and pectoral regions and abdominal wall.

This book will prove valuable for the purpose of reference to qualified medical practitioners, and senior medical students.

THE STUFF WE'RE MADE OF.—By W. O. Kermack, M.A., D.Sc., LL.D., and P. Eggleton, D.Sc. 1938. Edward Arnold and Company, London. Pp. viii plus 342. Illustrated. Price, 7s. 6d.

THIS small book was read with great interest by the reviewer, because it gives in clear and simple language a statement of the modern conception of atomic and molecular structure accompanied by examples drawn from everyday life. It also demonstrates the great importance in modern medicine of the subject styled 'bio-chemistry'.

Twenty years ago the detailed knowledge of how to investigate chemical reactions as they occur in the body as opposed to the test tube was a rare accomplishment almost exclusively confined to a group of specialized chemists without medical training. Nowadays medically trained individuals who are also skilled biochemists are numerous and the work they are doing necessitates all practitioners who wish to keep up with the times having at least a smattering of the subject and a clear knowledge of what such things as enzymes, amino-acids and polypeptides are, and what is meant by certain definite chemical groups such as methyl, carboxyl, etc.

This information will be found in the book under review and it is given in such clear language accompanied by simple and practical examples from daily experience that the reading of it is a real pleasure. It is strongly recommended to all students at the outset of their careers to enable them to approach the difficult subject of biochemistry with confidence, and in the reviewer's opinion it will be even more valuable to those doctors who qualified in pre-biochemistry days for it will turn their probably somewhat vague knowledge of the subject into a clear appreciation of

the main principles of this comparatively new branch of chemical science.

JALER PRAKRITI O PRAYOG. WRITTEN IN BENGALI.—By Dr. B. B. Pal, L.M.S. Published by N. B. Pal, 39/5/1A, Gopalnagar Road, Allpur, Calcutta. Pp. 66

THIS little book deals with physical properties, chemistry and uses of water. Hydrotherapy has been described in detail. The book will be found useful to the general public and Indian nurses.

Abstracts from Reports

ANNUAL REPORT ON THE WORKING OF HOSPITALS AND DISPENSARIES IN THE PRESIDENCY OF BENGAL FOR THE YEAR 1936. BY MAJOR-GENERAL D. P. GOIL, K.H.P., M.B., Ch.B., F.R.C.S.E., I.M.S., SURGEON-GENERAL WITH THE GOVERNMENT OF BENGAL

DURING the year under report there was marked improvement in the work of medical relief both in the Presidency town (Calcutta) and in the mofussil. The number of hospitals and dispensaries increased by 49, and 31 temporary dispensaries were made permanent. The number of beds in the hospitals increased by 506. The daily average of patients in the indoor departments increased by 130 in Calcutta and 140 in the mofussil, and that in the outdoor departments by 108 and 1,910, respectively.

X-ray installations are now available in 15 of the mofussil hospitals as against 12 in 1935.

The popularity of the hospitals both in Calcutta and in the mofussil is steadily growing.

The opening of the up-to-date and well-equipped Sir John Anderson Casualty Block in the Medical College Hospitals early this year with 40 beds and 4 cabins fills a great want and emergent cases can now be dealt with much more promptly than before.

The proposal of re-building the Lady Dufferin Victoria Hospital, Calcutta, with staff quarters, etc., made rapid progress during the year under report.

The Sadar hospitals in most of the districts have gained much in popularity with the opening of x-ray maternity, eye, ear, nose and throat clinics, the need for which was being felt more and more by the people in the mofussil. In order to facilitate the working of these special branches without entailing extra burden on Government and the local authority, a scheme for the employment of competent private medical practitioners in an honorary capacity has been evolved and approved by Government. It is hoped that with the co-operation of these qualified non-official workers the institutions in the mofussil will be able to render medical assistance of a much higher standard than has been possible hitherto.

The condition of Sadar hospitals as a whole, however, is still far from satisfactory. The resources of these institutions are being strained to their utmost capacity.

Medical aid in rural areas is still inadequate. There are now 1,102 hospitals and dispensaries in the rural areas, and apart from these there are reported to be 2,177 qualified private medical practitioners settled in such areas in the province. This makes a total of 3,279 practitioners in rural areas and allows on an average only one medical practitioner for over 13,740 people according to the census of 1931. Now that a large number of qualified medical men are coming out of the medical schools every year, ways and means must be devised to establish dispensaries in rural areas, so that better medical aid may be made available and means of livelihood may be found at the same time, for the new recruits to the profession.

Considerable increase in the number of tuberculous patients is noticeable in the figures. The question of

establishing a tuberculosis sanatorium in the province has been under consideration for the last three years. Thanks to the generosity of Babu Ram Kumar Bangur, who has come forward with a gift of Rs. 2,80,000 for the purpose, there are definite prospects of the scheme materializing before long.

In co-operation with the Public Health Department steps are also being taken to set up tuberculosis clinics at district headquarters hospitals possessing an x-ray plant and for a tuberculosis survey to be carried out.

ANNUAL PUBLIC HEALTH REPORT OF THE PROVINCE OF ASSAM FOR THE YEAR 1936. BY DR. S. H. PAUL, M.R.C.S. (ENG.), D.P.H. (LOND.), ETC., DIRECTOR OF PUBLIC HEALTH

THE total number of births registered during the year under review was 239,704, yielding a birth rate of 30.24 per 1,000 of population as compared with 239,898 and 30.26 respectively in the preceding year. The number of births registered in 1936 was lower than that recorded in 1935 by 194.

The total number of deaths registered during the year under report was 155,601, yielding a death rate of 19.63 per mille of population, as compared with 169,723 and 21.41 respectively in the preceding year. The quinquennial average was 19.80.

The state of health in the province during the year under review was satisfactory. Deaths under all heads of mortality with the exception of some increase under 'smallpox' were smaller during the year 1936.

A total of 155,601 deaths occurred during the year, viz, 3,816 from cholera, 963 from smallpox, 97,240 from fevers, 11,113 from dysentery and diarrhoea, 6,425 from respiratory diseases, 2,042 from injuries and 34,002 from all other causes.

Cholera.—The total number of deaths from cholera reported during the year was 3,816 as compared with 7,436 in 1935. The death rate per 1,000 population was 0.48 against 0.94 in the preceding year. The decennial average was 0.91.

Smallpox.—The total number of deaths from smallpox during the year under report was 963 as compared with 529 in 1935 showing an increase of 434 deaths. The death rate was 0.12 per mille as compared with 0.07 in 1935 and 0.30 the decennial average.

Fevers.—The total number of deaths from fevers during the year under review was 97,240 as compared with 106,719 in 1935. This shows a decrease of 9,479. The death rate per mille was 12.27 as compared with 13.46 in the preceding year and 11.97 during the last decennium as shown in the table.

Dysentery and diarrhoea.—The total number of deaths registered from dysentery and diarrhoea during the year was 11,113 as compared with 10,947 in 1935. The corresponding death rates for the two years were 1.40 and 1.38 respectively. The decennial average was 1.19.

Respiratory diseases.—A total of 6,425 deaths occurred from these diseases during the year under report as compared with 7,022 in the preceding year,

yielding, death rates of 0.81 and 0.89 respectively. The quinquennial average was 0.76.

Epidemic dropsy.—An outbreak of epidemic dropsy was reported from the area under Kulaura Police Station in the Sylhet district. An Epidemic Unit Sub-Assistant Surgeon was deputed to deal with the outbreak. He detected a large number of patients and directed them to undergo treatment in the Kulaura dispensary.

Yaws.—During the year under report 3,496 cases of yaws were treated against 4,201 in 1935. The decrease of 705 in the number of cases treated is mainly due to the fall in the Goalpara, Kamrup and Nowgong districts. The largest decrease (635) was in the Goalpara district. This was due to the fact that Goalpara Local Board did not provide adequate funds for drugs for the treatment of yaws cases in the local board dispensary.

Kala-azar.—The number of deaths from kala-azar was less in 1936 by 92 than that of the preceding year. The number of patients treated fell from 11,100 in 1935 to 10,587 in 1936. The conditions in individual districts appear to have remained practically the same as in previous year.

Leprosy.—During the year under report, 4,847 lepers received treatment in the leper asylums and other centres.

Maternity and Child Welfare

The number of child welfare centres during the year under report remained the same, viz. five as in the preceding year. The work of the *dai* training classes at Silchar, Karimganj and Sylhet was satisfactory during the year. The centre at Doom Dooma continued its work during the year. A total of 36,152 infants died during 1936, giving a rate of 150.82. During the year 99 infants died daily in the province. This appalling rate of mortality of infants can be reduced considerably if a larger number of up-to-date Maternity and Child Welfare centres are opened throughout the province and a larger number of midwives are made available.

NOTES ON THE ANNUAL RETURNS OF THE HOSPITALS AND DISPENSARIES IN BIHAR FOR THE YEAR 1936. BY LIEUT.-COL. H. STOTT, O.B.E., M.D., F.R.C.P.II., D.P.H., I.M.S., INSPECTOR-GENERAL OF CIVIL HOSPITALS

The special feature of this year was the separation of Orissa from the Province of Bihar and Orissa and its inauguration into a new province from the 1st April, 1936. For the sake of convenience the statistics for the whole year for the districts transferred to Orissa will be shown in the annual report for 1936 of that province.

The number of hospitals and dispensaries in the combined province was 690 at the beginning of the year. Out of these, 104 were transferred to the new province leaving 586 in Bihar. The year closed with the same number of hospitals and dispensaries as it opened with.

The total number of in-patients treated in the state, public, local fund, private aided and subsidized hospitals and dispensaries was 77,014 against 72,713 in 1935, the corresponding figures for the out-patients were 5,198,848 and 4,749,434 respectively. The increase in the number of patients during the year under report is satisfactory.

The total number of patients treated in all classes of hospitals and dispensaries in the province was 6,624,488 against 6,177,313 in 1935. The total number of beds available in all classes of hospitals and dispensaries was 3,402 for males and 1,726 for females. There were 5,485 deaths from various diseases in all hospitals and dispensaries in the province.

Tuberculosis.—A scheme for organizing the treatment of tuberculosis all round the province has been considered and a committee has been formed under the auspices of the King George V Memorial Fund Association to work it out, of which the Inspector-General

of Civil Hospitals, Bihar, is the Honorary Secretary. The aim of the committee is to open tuberculosis clinics at the headquarters of all the districts in the province.

Leprosy and lepers.—There are now five leper asylums and one leper colony in the province with total accommodation of 1,851. The number of leper residents in them in 1936 was 2,104 against 1,844 in 1935 and the number of out-door patients treated in these leper asylums and colony was 3,491 against 4,625 of 1935.

KING EDWARD VII MEMORIAL PASTEUR INSTITUTE AND MEDICAL RESEARCH INSTITUTE, SHILLONG. THE TWENTIETH ANNUAL REPORT FOR THE YEAR ENDING 31ST DECEMBER, 1936

Antirabic Section.—From the beginning of the year under review, the vaccine was prepared from the Paris strain of fixed virus instead of the Kasauli virus formerly used.

The introduction of Paris vaccine has not apparently been followed by the improvement hoped for. It is probable that the results of treatment might be improved by the use of the vaccine in larger doses comparable to those given by most Pasteur Institutes in India. This, however, involves a considerably more complicated system of dosage than that now used and it is doubtful how far the introduction of further complications is justifiable where most of the cases are seen and treated at out-centres where antirabic treatment is only a minor part of the work of busy medical officers. It must be remembered, however, when considering our results, that in an institute where comparatively few patients are treated, one or two deaths more or less, such, for example, as may result from an unlucky run of severe cases at a particular centre, make a very big difference in the general death rate. This year, for instance, one centre had four deaths out of 146 persons treated, but all four were bitten by rabid jackals—notoriously dangerous bites—and all had received severe multiple injuries. Two of these cases were bitten by the same animal, both bitten on the head, both started treatment a week later and one died during treatment. No form of treatment known at present could, it is believed, have saved these two cases.

There was one case of 'paralytic accident' during the year.

The history of the case, kindly supplied by the medical officer in charge of the centre, is as follows:—

D. F. D., European male, 35 years. Contact with a horse certified by a Veterinary Sub-Assistant Surgeon as rabid. The patient was put on class II treatment, i.e., 4 c.c. vaccine for 14 days.

The patient had been vaccinated on 6th April—very mild modified success.

10th April, 1936.—Antirabic treatment begun—4 c.c. daily from 10th to 16th April. Then ceased treatment against advice and went away for the week-end. Returned on 20th April with fever. Treatment resumed on 21st, 4 c.c. daily as before, but only continued for 3 days.

21st April. Headache and muscular pains.

22nd April. Painful spasms of muscles.

23rd April. Dull and apathetic—paresis of both legs with paræsthesia and loss of knee jerks.

24th April. Flaccid paralysis of both legs—all reflexes gone. The paralysis spread up to the umbilicus with paræsthesia and tingling and numbness of both hands and arms and paresis of the left forearm. Loss of sphincter control.

28th April. Condition has become stationary.

1st May. Slight signs of improvement. Some movement of left hand.

15th May. Plantar reflexes extensor, and muscular twitching in legs and thighs. Can open and close left hand. No knee jerks.

26th May. Left for home. Left hand and arm paresis much improved. Both legs paralysed, but signs of movement in the left leg.

9th July. Admitted to Tropical Diseases Hospital, London. Left leg nearly normal. Right improving slowly. With assistance can walk a few steps. Spastic paralysis of both legs with a positive double Babinski. Impairment of sensation up to the 5th thoracic segment.

Diagnosis.—Diffuse transverse myelitis.

21st September. Very slowly improving. Can walk 50 yards with 2 sticks and can climb upstairs with difficulty—right leg still worse than left.

May 1937. Condition considered stationary and no further improvement to be expected.

Assam Medical Research Society.—Research on the cold weather bionomics of *A. minimus* gives the following conclusions:—

(a) *A. minimus* bred out in January and February form a sufficient nucleus of this carrier species so that by early March, when the prevailing mean temperatures conduce to the completion of the sporogony cycle to the sporozoite stage, they can be responsible for active transmission after that period.

(b) Stream breeding experiments, with appropriate laboratory controls, show that *A. minimus* does not winter in the larval stage.

(c) Due to continuous cold weather breeding, notwithstanding the low minimum temperatures experienced in Assam plains, there is maintained a constant supply of adult *A. minimus* throughout the cold weather.

(d) Studies of the wing grades, ovarian stages and gut contents of adult *A. minimus* from December to March reveal no evidence of hibernation, over-wintering or gonotrophic dissociation.

(e) The detection of blood in different stages of digestion in 96 per cent of *A. minimus* caught at regular intervals from December to March and dissected on the same day they were caught, and the observation that ovarian development continued uninterrupted in 1,122 specimens dissected 8 to 18 days after capture, where the ovarian development observed must have been dependent upon blood feeds having been taken, gives evidence that the feeding stimulus of this species is not inhibited by the minimum temperatures prevailing when suitable micro-climates are available.

(f) There is no evidence to support the view that infected or uninfected *A. minimus* adults are carried over in the hibernating or other stages from November to March to be a responsible factor in the transmission of malaria in March.

(g) On dissection of *A. minimus* the oöcyst rate which was 4.8 per cent in December was reduced to 2.0 and 2.1 per cent in January and February, but was subsequently increased to 8.6 per cent in March.

(h) On dissection of *A. minimus* the sporozoite rate was 1.8 per cent in December, 0.3 per cent in January, nil in February and was increased to 2.6 per cent in March.

(i) The main factors considered responsible for reduction in the amount of transmission of malaria during January and February when mean temperatures are below 60°F. are (a) the relatively short life of the vector species *A. minimus* and (b) the lengthened time required for the completion of the sporogony cycle.

(j) The observations and findings described indicate that anti-larval operations directed specifically against *A. minimus*, to be effective in preventing the annual March-April rise in the malaria case incidence in the plains of Assam, should be started not later than 15th January, annually.

[In addition to this there is a long section devoted to the account of the cholera research carried out under a grant from the Indian Research Fund Association. This is of great interest but is somewhat technical for general readers so it is omitted. Workers in cholera should consult the original report.—EDITOR, I. M. G.]

THE REPORT ON THE PUBLIC HEALTH ADMINISTRATION OF THE PUNJAB FOR THE YEAR 1936

Vital statistics.—The Director of Public Health has given an interesting analysis of the vital statistics for the year, but the figures give ground for serious consideration, if not anxiety. The number of births recorded was 1,099,146 with a rate of 16.9 per mille of the census population, and the number of deaths recorded was 562,292 with a rate of 24 per mille. The natural increase in population on these figures is 536,854. The birth rate is the highest yet recorded for the province and is considerably higher than the rate for the whole of India. The death rate is the lowest on record except for the year 1922 and the natural increase is also a record. If this rate is maintained, the census of 1941 is likely to show a population for the province of about 28 millions as compared with 23.5 millions in 1931, and the question that arises is how this population is to subsist without a substantial reduction in the standards of living.

Fevers.—The number of deaths recorded under this head includes the greater part of all the deaths recorded during the year. The number of deaths from fevers was 374,817 which is the lowest figure since 1928. It is clear, however, from the report that little meaning can be attached to the figure as it includes deaths from a number of diseases of widely different character. The most important single disease under this head is malaria, the incidence of which is only very approximately known, but it is believed that about one-third of the deaths from fevers are due to malaria.

Smallpox.—There were 2,613 deaths from smallpox during the year, most of the cases being children under ten years of age. It would appear from the figures for recent years quoted in the report that smallpox is now on the upgrade again after two years of comparative immunity.

Cholera.—This disease is also on the increase and 1,721 deaths were reported, 26 districts being affected.

Plague.—This disease reached the lowest level for many years and only 153 deaths were reported. The distribution of the disease was limited to a few districts, mainly submontane, and the larger towns remained free from infection.

Tuberculosis.—The extent to which this disease prevails is not known, and the report shows that the number of reported deaths does not even approximately indicate its actual prevalence. It is only in the towns that the disease is notifiable, and even there the majority of cases are never reported until death occurs, and often not then.

Leprosy.—The leprosy survey of the province was continued and has now been completed in 15 districts. Twenty-eight new leprosy clinics were opened during the year, bringing the total to 80.

Hookworm.—The survey was continued and has been completed in 15 districts and the result shows that the disease is much more prevalent than was formerly imagined. Hookworm is probably responsible for much ill-health which was formerly attributed to other diseases, particularly malaria. The four treatment units in Gurdaspur district continued to work and 78,176 persons were treated.

Urban sanitation.—The standard of sanitation in Municipal towns remains lamentably low and the number of such towns that have both a satisfactory water-supply and adequate drainage is still small.

Rural sanitation.—The report shows that considerable improvements have been made in village sanitation. Five hundred and six new wells were constructed, over 6,600 were repaired and over 4,000 hand-pumps installed. One hundred thousand new refuse pits were dug, 264,120 feet of drains laid and 824,640 square feet of roadway paved. This was done mainly by the labour or material supplied by the villagers or by money contributed by them.

Maternity and child welfare.—The central institution in the Punjab for welfare work is the Public Health School which trains the health visitors for work in the health centres throughout the province. The

health school worked successfully throughout the year and trained 13 students all of whom passed the final examination and found posts at health centres. The demand for health visitors exceeds the supply and proposals for six new centres failed because the supply was not sufficient.

Inspection of schools and school children.—The inspection of school premises is carried out by medical officers of health, who inspected 667 primary and 364 secondary schools in addition to 27 colleges and 9 European schools.

REPORT OF THE RAMAKRISHNA MISSION SEVASHRAM CHARITABLE HOSPITAL, RANGOON. FOR THE YEAR 1937

DURING the year 1937, the total number of patients treated at the Sevashram was 92,793. These patients did not belong exclusively to the city of Rangoon, a considerable number of them came from the suburbs and from some remote districts of Burma.

The number of patients admitted in the indoor department during the year under review was 3,178 males, 1,044 females and 153 children. The aggregate of the daily totals of attendance came up to 37,354 males, 7,978 females and 1,168 children, i.e., a total of 46,530. The average daily attendance was 103 males, 22 females and 3 children, i.e., a total of 128. The average period of stay in the hospital in each case was nearly 11 days. Some chronic cases had to be kept for months.

At the out-patients department the total number of attendances came up to 239,369 including men, women and children. The average daily attendance was 427 men, 133 women and 96 children, i.e., a total of 656.

Service Notes.

APPOINTMENTS AND TRANSFERS

MAJOR-GENERAL H. C. BUCKLEY, K.H.P., returned from leave and resumed charge of the duties of the Surgeon-General with the Government of Bombay, with effect from the forenoon of 7th November, 1938.

Colonel F. F. S. Smith to be Officiating A. D. M. S., Peshawar District. Dated 23rd September, 1938.

Colonel A. C. Munro to be A. D. M. S., Western Independent District. Dated 1st November, 1938.

The Secretary of State for India has appointed to the Civil Branch of the Indian Medical Service the undermentioned officers of the Service, with effect from the 1st April, 1937. They will count their seniority in civil employment from the dates noted against their names:—

Lieutenant-Colonel J. H. Smith. Dated 7th April, 1920.

Lieutenant-Colonel A. J. D'Souza, M.C. Dated 5th March, 1934.

Lieutenant-Colonel W. J. S. Ingram, M.C. Dated 13th March, 1919.

Lieutenant-Colonel R. C. Phelps. Dated 16th July, 1921.

Lieutenant-Colonel D. P. McDonald. Dated 8th December, 1934.

Lieutenant-Colonel G. C. Maitra. Dated 29th September, 1920.

Lieutenant-Colonel H. H. Barrett. Dated 16th July, 1924.

Lieutenant-Colonel S. M. A. Faruki to be Specialist in Ophthalmology, Rawalpindi District. Dated 30th September, 1938.

Lieutenant-Colonel R. Lee to be Officer Commanding, Indian Military Hospital, Jubbulpore. Dated 23rd October, 1938.

Lieutenant-Colonel R. Sweet, D.S.O., to be Officer Commanding, Indian Military Hospital, Peshawar. Dated 25th October, 1938.

Lieutenant-Colonel H. J. M. Cursetjee, D.S.O., to be Officiating Officer Commanding, Indian Military Hospital, Quetta. Dated 21st October, 1938.

On reversion to the Medical Stores Department on completion of his tenure of appointment as Assistant Director-General, Indian Medical Service (Stores), Lieutenant-Colonel W. M. Will, M.B., Ch.B., I.M.S., assumed charge as Officer in charge, Medical Store Depot, Bombay, on the afternoon of the 31st October, 1938, relieving Major W. T. Taylor, I.M.S., on transfer to Lahore Cantonment.

Lieutenant-Colonel C. deC. Martin was appointed Civil Surgeon, Rangoon (East), vice Captain H. Min Scin, from the forenoon of the 5th November, 1938.

Lieutenant-Colonel R. V. Morrison on return from leave was appointed First Physician, Rangoon General Hospital, vice Lieutenant-Colonel C. deC. Martin, from the forenoon of the 5th November, 1938.

On return from leave Lieutenant-Colonel N. Briggs took over charge of the office of the Director of Health Services and Inspector-General of Prisons, Sind, from Lieutenant-Colonel B. Z. Shah on the afternoon of the 9th November, 1938.

Lieutenant-Colonel J. S. S. Martin to be Officer Commanding, Indian Military Hospital, Meerut. Dated 9th November, 1938.

Lieutenant-Colonel S. L. Bhatia, M.C., returned from leave and resumed charge of the duties of the Principal, Grant Medical College, and Superintendent, J. J. Group of Hospitals, Bombay, (with effect from the forenoon of 12th November, 1938).

Lieutenant-Colonel A. C. Craighead to be Officiating A. D. P., Southern Command, and Officer in charge, Southern Command Laboratory, Poona. Dated 15th November, 1938.

The Secretary of State for India has appointed to the Civil Branch of the Indian Medical Service the undermentioned officers of the Service, with effect from the 1st April, 1937. They will count their seniority in civil employment from the dates noted against their names:—

Major V. S. R. Pandit. Dated 29th June, 1934.

Major C. H. Fraser. Dated 31st December, 1932.

Major P. A. C. Davenport. Dated 16th February, 1932.

Major R. McRobert. Dated 29th January, 1932.

Major G. J. Smith. Dated 2nd November, 1936.

Major T. J. Davidson. Dated 14th July, 1933.

Major C. A. Bozman. Dated 13th March, 1935.

On return from leave Major R. A. Wesson has been posted as Civil Surgeon, Gorakhpur.

Major A. N. Duggal to be D. A. D. P., Waziristan District. Dated 6th October, 1938.

Major D. C. Chopra joined the Indian Military Hospital, Alipore, for duty, on return from China, on the 12th October, 1938.

On completion of his term of office at Dalhousie, Major P. C. Dutta assumed charge of the office of the Civil Surgeon, Gujrat, on the forenoon of the 27th October, 1938.

Major M. K. Kelavkar, M.B.E., Officer in charge, Medical Store Depot, Lahore Cantonment, on transfer to New Delhi with a view to his appointment as Assistant Director-General, Indian Medical Service (Stores), made over charge of that Depot to First Class Military Assistant Surgeon E. Duckworth, M.B.E., on the afternoon of the 20th October, 1938.

Major M. K. Kelavkar, M.B.E., was transferred to civil employment for duty as Assistant Director-General, Indian Medical Service (Stores), on the afternoon of the 20th October, 1938.

On completion of his term of duty at Murree, Major B. Temple Raston assumed charge of the office of Civil Surgeon, Attock District, Campbellpur, on the forenoon of the 1st November, 1938.

Major L. F. Burns to be Staff Captain (Medical), Western Independent District. Dated 1st November, 1938.

On transfer from Bombay, Major W. T. Taylor assumed charge as Officer in charge, Medical Store Depot, Lahore Cantonment, on the forenoon of the 4th November, 1938, relieving Assistant Surgeon E. Duckworth, M.B.E., of the additional charge.

On his return from leave Major H. S. Waters has been re-appointed as Presidency Surgeon, Bombay, with attached duties, with effect from the forenoon of 4th November, 1938, *vice* Captain A. A. Pullar, transferred.

Major W. F. Cooper was transferred to civil employment under the Port Health Officer, Bombay, on the 9th November, 1938.

Major B. D. Khurana to be Officiating D. A. D. H., Rawalpindi and Waziristan Districts. Dated 15th November, 1938.

Major E. A. R. Ardesir was transferred to civil employment in Bengal on the 26th November, 1938.

The Secretary of State for India has appointed to the Civil Branch of the Indian Medical Service the undermentioned officers of the Service, with effect from the 1st April, 1937. They will count their seniority in civil employment from the dates noted against their names:—

Captain C. F. J. Cropper. Dated 19th June, 1935.

Captain W. McAdam. Dated 4th August, 1934.

Captain A. E. Kingston. Dated 17th November, 1936.

Captain R. L. Raymond. Dated 11th November, 1936.

Captain D. K. Lindsay. Dated 17th December, 1935.

Captain M. S. Purvis. Dated 21st November, 1936.

Captain C. C. Kapila. Dated 3rd June, 1936.

Captain H. Min Sein was placed on special duty attached to the Pathology Department at the Rangoon General Hospital to enquire into the system of indigenous drugs in Burma.

Captain P. B. Cusack to be Officiating Officer in charge, Brigade Laboratory, Abbottabad. Dated 1st October, 1938.

Captain T. P. Mulcahy to be Officiating Specialist in Gynaecology and Obstetrics, Meerut District. Dated 9th October, 1938.

On return from combined leave granted by Headquarters, Army in Burma, Captain J. D. Murdoch joined the Indian Military Hospital, Quetta, for duty on the 11th October, 1938.

Captain H. T. McWilliams to be Staff Captain (Medical), Western Independent District. Dated 1st November, 1938.

Captain M. G. Leane departed from the C. I. M. H., Loralai, for duty, with the Army in Burma, on the 11th October, 1938.

Captain J. W. Bowden was transferred to civil employment in Orissa on the 11th October, 1938.

Captain A. K. Dev to be Specialist in Surgery, Deccan District, Jabulpore. Dated 21st October, 1938.

Captain R. D. Scriven embarked from Calcutta for a tour of service in China on the 3rd November, 1938.

Captain J. H. Walters to be Staff Surgeon, Poona. Dated 7th November, 1938.

Captain S. A. Mian to be Surgical Specialist, Waziristan District, Bannu. Dated 7th November, 1938.

Captain A. A. Pullar has been appointed to officiate as Civil Surgeon, Belgaum, with attached duties, with effect from the forenoon of 11th November, 1938.

On transfer from the Military Department Captain F. V. Stonham assumed charge of the office of the Civil Surgeon, Dera Gazi Khan, on the forenoon of the 21st November, 1938.

Reverted from civil employment

Captain C. J. H. Brink, Residency Surgeon, Kashmir, on the 27th November, 1938.

Captain W. V. Stiver from Bihar, on the afternoon of the 12th November, 1938.

Captain S. M. Kharegat joined the Indian Military Hospital, Poona, for duty, on return from China, on the 28th November, 1938.

Lieutenant (on probation) C. W. Greene is restored to the Establishment from 1st January, 1938, with seniority, 1st January, 1937. (Substituted for the previous notification.)

To be Lieutenants (on probation)

1st September, 1938

Malcolm Duncan Black, with seniority 1st March, 1937.

George John Haley Maud, with seniority 1st March, 1937.

Ian Donald Sutherland, with seniority 1st March, 1937.

John James Woodward, with seniority 1st September, 1937.

Sydney Hayden Heard, with seniority 1st September, 1937.

Charles Graham Riley, with seniority 1st September, 1937.

Herbert Richard Loughran, with seniority 17th October, 1937.

Donald James Patrick Spillane, with seniority 18th January, 1938.

Patrick Murdoch Kirkwood, with seniority 12th February, 1938.

James Andrew Anderson.

John Alexander Munro Cameron.

Leonard Henry Cooper.

Douglas Spencer Wilson.

Peter John Wormald.

William Stanley Hacon.

The undermentioned officers are restored to the Establishment:—

Lieutenant (on probation) J. E. Ennis, 1st September, 1938, with seniority 1st September, 1937. (In substitution of the previous notification in the *Gazette* of the 16th September, 1938.)

Lieutenant (on probation) J. M. M. Drew, 15th October, 1938.

The following officers arrived in India on first appointment on the dates shown opposite their names:—

Lieutenant N. D. Jekyll. Dated 28th September, 1938.

Lieutenant G. A. Graham. Dated 28th September, 1938.

Lieutenant D. McC. Black. Dated 28th September, 1938.

Lieutenant J. H. Briscoe-Smith. Dated 28th September, 1938.

Lieutenant A. C. Glendinning. Dated 28th September, 1938.

Lieutenant J. G. Fife. Dated 28th September, 1938.

Lieutenant G. C. Retz. Dated 12th October, 1938.

Lieutenant R. D. D. Birdwood. Dated 12th October, 1938.

Lieutenant A. R. Woodforde. Dated 12th October, 1938.

To be Lieutenants (on probation)

1st November, 1938

E. J. Somarset, with seniority 1st May, 1937.

L. D. B. Frost, with seniority 1st May, 1937.

A. M. Mackenzie, with seniority 1st May, 1937.

J. L. M. Whitbread, with seniority 1st November, 1937.

G. T. Hayes.

O. T. Mansfield.

J. P. O'Riordan.

R. N. Houlding.

Lieutenant J. W. Lillico arrived in India, on first appointment, on the 26th November, 1938.

LEAVE

On relief by Major-General H. C. Buckley, K.H.P., Lieutenant-Colonel M. J. Holgate, O.B.E., has been granted leave on average pay for 6 months, with effect from the forenoon of 7th November, 1938.

Lieutenant-Colonel H. S. Cormack was granted an extension of 20 months' leave preparatory to retirement.

PROMOTION

Lieutenant-Colonel to be Colonel

D. F. Murphy, M.C. Dated 16th October, 1938, with seniority from 1st January, 1934.

Major to be Lieutenant-Colonel

J. Carrey. Dated 24th October, 1938.

Captains to be Majors

W. McAdam. Dated 6th August, 1938.

T. D. Ahmad. Dated 6th October, 1938.

B. N. Khan. Dated 2nd November, 1938.

A. M. Chaudhuri. Dated 6th November, 1938.

RETIREMENTS

Lieutenant-Colonel A. N. Palit, O.B.E. Dated 4th October, 1938.

Colonel J. Scott, D.S.O., O.B.E., on account of ill health, 16th October, 1938.

Lieutenant-Colonel F. M. Kirwan. Dated 23rd October, 1938.

Lieutenant-Colonel F. Stevenson. Dated 28th October, 1938.

Lieutenant-Colonel N. B. Mehta. Dated 5th November, 1938.

Notes

EUCERINUM ANHYDRICUM FOR OINTMENTS

AN IDEAL VEHICLE

EUCERINUM ANHYDRICUM is a mixture of eucerit, which is a water-fixing alcohol of the meta-cholesterol series, isolated by Lifschutz, with pure, neutral and chemically indifferent hydrocarbons. It will keep indefinitely, has no odour, is non-irritant, and can easily take up 200-300 per cent of water or watery solutions, forming permanent and homogeneous mixtures. It is, therefore, the most suitable vehicle for fluid medicaments and for solutions of medicinal substances, such as liq. Hamamelidis, hydrogen peroxide, glycerin, etc.

Eucerinum anhydricum absorbs fatty and watery secretions of the skin with equal ease. It will even adhere to damp mucous membranes, and is, thus, the basis of ointments intended for mucosæ, such as the eyes, nose, lips, ears and vagina.

Eucerinum (*cum aqua*) is a homogeneous mixture of equal parts of eucerinum anhydricum and water. Even without the addition of any medicinal agent, it is a most excellent bland ointment. The coolness produced by the evaporation of its water-content reduces the temperature of the skin. It, therefore, affects all inflammatory lesions of the skin in the same way as a cold bandage, reducing irritation and cooling the parts. On account of its fat content it softens roughened skin, and, just like Nivea creme, has a wide field of application for this purpose.

Eucerinum (*cum aqua*), on account of its even mixture of fatty and watery constituents, is absorbed into the skin without any difficulty. As was first pointed out by Unna, when treating cases of rosacea, eucerinum (*cum aqua*) forms a most excellent means of cleaning the facial skin in cases where soap and even water are harmful. As eucerinum has a composition very much like that of the skin secretions themselves, it is very easily absorbed by the skin. It is, therefore, specially suitable as a basis for ointments containing insoluble, powdery medicaments, which can exert a deep effect only in this way.

'CAMPOFERRON'

BAYERS REMEDIES LIMITED, the sole importers for India, Burma and Ceylon of 'Bayer' preparations, beg to announce to the profession the introduction of 'Campoferron', a hæmationic preparation for oral use on the basis of 'Campolon', iron and copper. Owing

to its peculiar combination 'Campoferron' is indicated in all forms of hypochromic anæmia. Further, owing to its pleasant taste and good tolerability, 'Campoferron' allows prolonged administration, and is acceptable to all types of patients.

CARDIAZOL-EPHEDRINE-KNOLL

CARDIAZOL-EPHEDRINE-KNOLL is a combination of cardiazol and ephedrine, the former exerting a direct action on the vasomotor centre, the latter an excitant of the sympathetic vascular nerve-endings. The combination thus represents a remedy of central and peripheral action. Its great advantage is that the onset of action is quicker than after ephedrine alone, and the duration of action is longer than after cardiazol alone. An important point in favour of the remedy is the high degree of tolerance in all cases. The combination is marketed in the form of tablets, in liquid form (drops) and in ampoules. Since both components possess spasmolytic properties, cardiazol-ephedrine is especially indicated in bronchial asthma, but has, above all, proved of great value in status asthmaticus, in asthma of long standing, and alteration, more particularly of the right heart. In view of its excellent tolerability, oral administration of cardiazol-ephedrine over long periods may be undertaken without hesitation; in acute asthma attacks the physician will, of course, resort to subcutaneous injection. Great benefit can be derived from this central and peripheral remedy also in the treatment of circulatory insufficiency, hypotonia and collapse.

Publishers' Notice

SCIENTIFIC Articles and Notes of interest to the profession in India are solicited. Contributors of Original Articles are entitled to receive 25 reprints *gratis*; additional reprints can be obtained on payment. No reprints will be supplied unless contributors ask for them at the time of submitting their manuscripts.

Communications on Editorial Matters, Articles, Letters and Books for Review should be addressed to THE EDITOR, *The Indian Medical Gazette*, c/o The Calcutta School of Tropical Medicine, Central Avenue, Calcutta.

Communications for the Publishers relating to Subscriptions and Advertisements should be addressed to THE PUBLISHERS, *The Indian Medical Gazette*, P. O. Box No. 54, Calcutta.

Annual Subscription to 'The Indian Medical Gazette', Rs. 16 including postage, in India. Rs. 19-8 including postage, abroad. Single copies Re. 1-8 each. Back numbers (if available) for the previous year Rs. 2-8 each, and all other back numbers Rs. 5 each.

Subscribers who so desire may have their copies packed flat in a strong envelope. The extra charge per annum is Re. 1-8 which should be added to the subscription. The envelopes are strongly made, and the *Gazette* is not folded, nor creased, in transit.

Papers and articles forwarded for publication are understood to be offered to *The Indian Medical Gazette* alone, and any breach of this rule will be followed by non-publication. When any such article appears in the *Indian Medical Gazette*, the copyright automatically becomes the joint property of the author or authors, and of the publishers.

The Editors of *The Indian Medical Gazette* cannot advise correspondents with regard to prescriptions, diagnosis, etc., nor can they recommend individual practitioners by name, as any such action would constitute a breach of professional etiquette.

CHRONIC ULCERATIVE COLITIS

By R. N. CHOPRA, C.I.E., M.A., M.D., Sc.D. (Cantab.),
F.R.C.P. (Lond.)

MBRET-COLONEL, I.M.S.

Honorary Physician to the King,

Director of the Calcutta School of Tropical Medicine
and

P. N. RAY, B.A., M.B. (Cal.), F.R.C.S. (Eng.)

Additional Surgeon, Medical College Hospitals, Calcutta

THE problem of ulcerative colitis remains unsolved; medical opinion has oscillated between the extremes of optimism and pessimism. There are some, notably Bergen (1935) and Buie (1937), who would class it among the conquered diseases, while others, Hetenyi (1935) for instance, would classify it equally emphatically among the incurable diseases. The significance of such startling divergence of authoritative opinion will be missed unless we take into consideration the geographical distribution of the disease and the changes in dietetics and habits, induced by the complexities of modern civilization. The consensus of medical opinion is more inclined to regard it in the same light as pulmonary tuberculosis; the disease can only be arrested by prolonged treatment, involving rest in bed and maintenance of mental peace. Spontaneous intermissions are not uncommon, but intercurrent infections and emotional disturbances have marked deleterious effects on the progress of the disease.

This paper is based on the study and statistical survey of 120 cases of ulcerative colitis under our care in the Medical College Hospitals and the Carmichael Hospital for Tropical Diseases. The present investigation was undertaken as a supplement to our previous work on 'Amoebiasis and Appendicitis' (Banerji, Chopra and Ray, 1936), wherein it was observed that the incidence of non-specific colitis in a small series of cases for sigmoidoscopy was as high as 43 per cent.

Definition.—Chronic ulcerative colitis may be regarded as a disease of the large intestines during the second and third decades of life with characteristic clinical and pathological features but without any specific bacteriological infection.

The effects of allergy, avitaminosis, faulty body mechanics and emotional disturbances have yet to be precisely determined. The view that, like peptic ulcer, it may be a local manifestation of a general disease has much to recommend it but requires confirmation.

Ætiology

There is still considerable confusion in the description of ulcerative colitis. From available evidence, it appears that in a variable percentage of cases no bacteriological relationship can be

established. Neither is there any unanimity of opinion regarding the ætiological factors, although it is customary to refer to various predisposing causes. We shall therefore briefly discuss the present position.

1. *Bacillary dysentery.*—Chronic ulcerative colitis has often been regarded as a sequela to bacillary dysentery. Penner (1936) is of opinion that, in the tropics, a large percentage of cases belongs to this category, while Hurst (1931) strongly advocated the use of antidysenteric serum. Our experience does not seem to confirm this view (Chopra, Hayter and Bhattacharya, 1937). It is a curious fact that children appear to be immune from ulcerative colitis, although they are known to suffer from bacillary dysentery and its usual terminal complications (Ray, 1934).

2. *Amoebic dysentery.*—*Entamoeba histolytica* has also been regarded as a causative agent, but this view has not been confirmed by laboratory and other evidence.

3. *Streptococcal infection.*—In recent years, much attention has been paid to the investigation of a possible bacterial origin of chronic ulcerative colitis. Bergen (1935) is of opinion that a diplococcus, isolated by him from ulcers of the colon, is the cause of the disease. Intravenous injections of Bergen's diplococcus in the rabbit are said to produce diarrhoea with blood and mucus, but it cannot be said that the experimental disease bears any resemblance to the chronic ulcerative colitis in man. It is, however, important to note that this disease is prone to occur in association with infections of the upper respiratory tracts, e.g., coryza, tonsillitis, recurrent pharyngitis, and sinusitis. Influenza would seem to require special mention. The incidence of streptococcal infection in ulcerative colitis has varied within wide limits in the hands of different workers. There is no doubt of a streptococcal relationship in some cases although the question has yet to be answered, whether the infection is primary or secondary. In our hands the figures are far from convincing. The empirical administration of 'Prontosil' and anti-streptococcal serum in a number of control cases has not been marked with any tangible success.

4. *Avitaminosis.*—There is little doubt that persistent deficiency of vitamin C in the diet is an important predisposing factor in the causation of recurrent hæmorrhages from the bowel in case of chronic ulceration of the colon. In a few cases we have obtained very satisfactory results with the administration of vitamin C ('Cantan', Bayer). Uniformly good results have also been reported by Hetenyi (1935). Familiarity with the beneficial effects of cod-liver oil as a local application in various kinds of ulceration led us to try it as a local instillation in ulcerative colitis. The result was a pleasant surprise. Similar results have also been reported by Spiegel (1937) and the improvement is ascribed to the presence of vitamins A and D. We cannot exclude a reference to the vitamin-B

complex. As a dietary adjunct in the treatment of ulcerative colitis, it is generally indicated and for this purpose 'marmite' has given consistently good results. In spite of accumulated evidence, it is not yet justifiable to include ulcerative colitis in the group of the 'deficiency diseases'.

5. *Allergy*.—The question of allergy cannot be dismissed without careful consideration. In about 20 per cent of cases a positive history of allergy with regard to some specific foodstuff is obtained, and here 'Torantil' (Bayer) has been found to be of use. In two cases, the remarkable history was obtained that an improvement of the colitis was invariably noticed with the appearance of eczematous patches on the body. In another case, the onset of bronchial asthma would definitely bring about an amelioration of symptoms. Chronic ulcerative colitis presents some features comparable to those of chronic eczema or neuro-dermatosis.

6. *Faulty body mechanics*.—Poor body mechanics may give rise to functional disturbances of the colon to which have been attributed a long list of ailments ranging from indigestion to neurasthenia, and from auto-intoxication to arthritis. The primary factors in the production of these symptoms are chronic passive congestion, stasis and disturbed innervation, which may be caused by the abnormal position of the internal organs always found in faulty posture (Goldthwait, Brown, Swain and Kuhn, 1937).

7. *Emotional disturbances: 'Tropical Neurasthenia'*.—It is a curious fact that exacerbations of chronic colitis are, in nearly 50 per cent of cases, associated with some previous emotional disturbances of a serious nature. The similarity of this aspect of the disease to peptic ulceration is worthy of note.

8. *Other causes*.—In a disease of unknown origin the list of probable causes cannot be easily exhausted. Intestinal parasites which are so common in tropical countries have also been blamed for more than one symptom. Irregularity of hours, unsuitable dietary, addiction to drugs, and smoking and enteritis following typhoid and other exanthems have all been regarded as possible exciting causes.

To sum up, we are constrained to state that we are unable to determine any single ætiological factor for ulcerative colitis. It is probable that many factors combine to produce devitalization of the mucous membrane of the large intestines leading to chronic ulceration.

Pathology

The pathological concept has gradually veered round to the position that the lesion is not restricted to the mucosa but involves the sub-mucosa and, in later stages, the muscular coats. Although the ulceration is usually confined to the large gut, in severe old-standing cases it may extend to the adjacent part of the ileum. The parts most involved are the rectum, sigmoid, and the cæcum. The post-mortem appearances do

not give a correct idea of the disease, because the gross changes which are found in the later stages are considerably modified by the appearance of many complications and sequelæ.

Macroscopic appearances.—The naked-eye appearances of the mucous membrane may be carefully studied with the help of the sigmoidoscope. As the sigmoidoscopic appearances are characteristic, diagnosis is not difficult and, for convenience of clinical description, the lesions may be described in several stages. It is necessary to remember that, in the old-standing cases, these different stages cannot be strictly differentiated owing to considerable overlapping of signs, resulting from recurrent exacerbations. In the *first stage*, the mucous membrane of the rectum and the sigmoid colon shows signs of hyperæmia and inflammation (plate V, figure 1). The slightest trauma during instrumentation will give rise to bleeding. In the *second stage*, the œdematous mucosa, studded with numerous greyish-yellow granules, cannot be mistaken by the trained observer (plate V, figure 2). The transverse folds of the colon lose their sharp outline and become rounded and œdematous. The greyish-yellow granules represent minute necrotic foci or areas of degeneration under the unbroken lining epithelium. In the *third stage*, the greyish granules, having broken down, give rise to minute multiple ulcers producing a moth-eaten appearance to the mucous membrane (plate V, figure 3). The bleeding is due to the oozing from these ulcers and at times may occur in alarmingly large quantities. The *healing stage* will show multiple pale ulcers, which can only be described as indolent, and scattered scars (plate V, figure 4). In the more *chronic stage*, obliteration of the rectal valves, thickening of the mucosa, the presence of multiple granular vascular polyps and narrowing of the lumen, complete a characteristic picture (plate V, figure 4). There is another group of cases, in which large chronic ulcers are found scattered, showing little sign of healing (plate V, figure 5) owing to supervention of secondary infection from the contents of the alimentary tracts.

The *active or third stage* of chronic ulcerative colitis may assume a virulent form, characterized by severe pyrexia, widespread ulceration and marked prostration. It is necessary that in such cases great care should be exercised during sigmoidoscopic examination, otherwise there is danger of severe hæmorrhage or even perforation (plate V, figure 6). The lumen of the gut becomes markedly constricted and the friability of the soft tissues increases the dangers of instrumentation.

Histological appearances.—Owing to the protracted nature of the disease and absence of mortality in the early stages materials for histological study cannot be procured easily. The obvious difficulties of biopsy require no explanation; sections of the mucosa alone are not sufficient, and section through all the coats

of the large gut is a formidable procedure which cannot be lightly undertaken. Deaths during the early stages are usually due to other intercurrent diseases and, in the later stages, to various complications and sequelæ.

At an early stage of the disease, when the mucosa is inflamed but no ulcers have yet appeared, the microscopic picture consists of dilatation of the smallest capillaries, diapedesis and minute hæmorrhages. But the histological appearance of the granular non-ulcerated mucosa is very different and significant; it presents a homogeneous area with scanty cellular elements. There are pyramidal areas under the mucosa showing degenerative changes corresponding to occlusion or thrombosis of the deeper vessels.

This picture is considerably modified when sections are made through the moth-eaten granular mucosa, which reveal multiple miliary ulcers (plate VI, figure 7). The pin-head areas of degeneration or the miliary necrotic foci ultimately break down forming the characteristic chronic ulcers. These degenerated areas consist of hyaline material and are surrounded by some round-celled infiltration and fibrous tissue, sometimes very well marked, indicating the chronicity of the lesion (plate VI, figure 8). Similar changes are also found scattered throughout the different coats of the gut. The destruction of the lining epithelium appears to be gradual while the degenerative changes continue their steady course in the surrounding connective tissue (plate VI, figure 9). It is worthy of note that even fibrosis of these degenerated areas is a very slow and, probably, an incomplete process. Endarteritis obliterans is nowhere to be seen. The histological picture appears to be a very definite and characteristic entity, such as is seen in no other ulceration of the large intestines.

Quiescent periods.—In the intervals between the acute exacerbations of colitis, there are varying periods of intermission of symptoms. It is doubtful if the ulcers are completely healed during these periods. The analogy to duodenal ulceration is very close in this respect. The sigmoidoscopic appearance consists of pock-like scars, on a pale and 'glazed' mucosa. Microscopic sections will naturally show a variable amount of submucosal fibrosis.

Ulcers due to secondary infection.—It has already been pointed out that secondary ulcers usually supervene upon the miliary moth-eaten ulcers of chronic ulcerative colitis. These are caused by the invasion of the ulcerated area by the pathogenic organisms inhabiting the lower alimentary tract. In the very chronic cases, these secondary ulcers may be very widespread, causing a great deal of fibrosis and stenosis of the lumen. During the quiescent period, they may present the characters of superficial callous ulcers, but during an acute exacerbation, they may be transformed into deep penetrating or excavating ulcers, not infrequently simulating malignancy.

Complications and sequelæ.—With each acute exacerbation, the functions of the large intestines, *viz.*, absorption of fluid and motility of peristalsis, are grossly interfered with. Owing to extension of ulceration, fibrosis of the muscular coats, and destruction of the lining epithelium, diarrhœa and mucous discharge may become intractable, making the patient a chronic invalid. Recurrent rectal hæmorrhage may endanger life and give rise to severe anæmia. The bleeding is usually bright red, but mælena is not uncommon, indicating bleeding from the cæcum and the proximal colon. Stenosis of the lumen is a constant feature of the chronic cases; when well marked the lower colon, and in particular the rectum, become converted into an unyielding narrow tube lined with chronic indolent ulcers, giving rise to purulent and hæmorrhagic discharge. The diagnosis of these cases may be very difficult. Perforation, adhesions, pericolitis and fistulæ-in-ano may be regarded as other important sequelæ.

The extent and distribution of these pathological changes vary a great deal, and in cases operated upon it was found that all the coats of the colon were involved. The lymphatic glands in the mesentery and sigmoid mesocolon are invariably enlarged and œdema of the mesocolon is also common. It has not been possible to determine yet whether this is not due to a secondary infection. It is, however, worthy of note that the lymphatic nodules of the intestines, unlike those in typhoid fever, remain fairly healthy. Capillary thrombosis, hyaline degeneration and infarction appear to be the main histological lesions, but these findings are unknown in chronic colitis associated with bacillary dysentery and gummatous ulcers. It is somewhat difficult to explain the occurrence of such extensive ulceration as being wholly due to devitalization, resulting from impaired vascular supply. Such a widespread lesion, associated with endarteritis obliterans, is not even seen in course of syphilitic ulceration of the colon. The hæmorrhage is usually caused by the ulcers, but the so-called granular 'polyps', which are masses of granulation tissue, may at times be responsible. These are comparable to the nodules seen in epidemic dropsy.

Bacteriology

In the analysis of our cases we have not been able to point to any particular organism as the exciting cause. There is no evidence to show how the infective organisms invade so large an area of the gut. Even in the earlier stages, an extensive area of the gut is involved. There is no evidence to show that the disease is liable to appear at any particular region of the colon or to spread in any particular direction. In spite of every care in the majority of cases, no growth could be obtained on culture of the scrapings of ulcers. The bacterial examination of fæces may be found of interest in this connection.

TABLE I.

Microscopical examination of fæces in 100 cases

Helminths—		
<i>Trichuris trichiura</i> eggs	3
Hookworm eggs	8
Protozoa—		
<i>Giardia</i> cysts	5
<i>Entamoeba histolytica</i> —		
Vegetative forms only	1
Cysts only	2
Vegetative forms and cysts	1
Charcot-Leyden crystals	4

As ankylostomiasis is fairly widespread in this part of the country, its coincidence with ulcerative colitis is not significant.

Amœbic dysentery is common in India. A routine examination of the fæces of patients admitted into the Carmichael Hospital for Tropical Diseases showed an incidence of 12 per cent of infections with *E. histolytica* (Chopra, 1936). In the present series the incidence is only 4 per cent. These cases were treated for amœbiasis and the stools were examined repeatedly until they were negative for the parasite. The association of Charcot-Leyden crystals with amœbiasis does not appear to be of any significance.

TABLE II

Cultural examination of fæces in 100 cases

Organisms	Present survey	Chopra, Hayter and Bhattacharya (1937)
<i>B. pseudo-carolinus</i> ..	14	20
<i>B. asiaticum</i> ..	11	5
<i>B. carolinus</i> ..	8	Nil
<i>Ps. pyocyanea</i> ..	7	5
<i>Strepto. faecalis</i> ..	4	1
<i>Bact. alkaligenes</i> ..	3	18
<i>B. pseudo-asiaticum</i> ..	3	3
<i>B. morgani</i> ..	2	5
<i>B. meta-alkaligenes</i> ..	2	1
<i>B. flexner</i> ..	2	Nil
<i>B. shiga</i> ..	1	Nil
Monilia ..	1	Nil

The incidence of bacillary dysentery was only 3 per cent and it compares very favourably with that of amœbiasis. The non-dysenteric character of chronic ulcerative colitis is therefore clearly indicated. *Streptococcus faecalis* was isolated in only 4 per cent of cases. We have included *Ps. pyocyanea*, *Bact. morgani*, *B. carolinus* and *B. meta-alkaligenes* in this investigation because there are good reasons for believing that they might cause intestinal disorder.

Scrapings from the ulcers of the rectum and sigmoid showed the presence of Gram-positive cocci on three occasions. Other organisms isolated were a Gram-positive spore-bearer, staphylococci, a Gram-positive bacillus, a Gram-negative bacillus, and diphtheroids on one occasion each; these findings indicate the non-specific character of these ulcers.

It would appear to be extraordinary that no better information could be obtained by careful examination and culture of the scrapings of these ulcers. It may be objected that the infection is deep seated and therefore no further information could be obtained from the scrapings of comparatively superficial tissues from the floor of the ulcers.

Culture of blood.—It was hoped that by adopting special measures a conclusive result might be obtained, but a positive bacterial finding was an exception rather than the general rule, and in only two out of twenty cases spore-bearing organisms were isolated after forty-eight hours. No pathogenic organisms were isolated.

Investigations and diagnosis

Cases of ulcerative colitis are generally treated as dysentery before any surgical advice is sought, consequently the early stage, which is the best for chances of recovery, is seldom seen by the surgeon. Much valuable time is usually lost by treatment for hypothetical parasitic infections. On an average we get a history of three or four years' recurrent attacks of indigestion, diarrhoea and dysentery with repeatedly negative stool reports. In these chronic cases a great deal of care and caution would be necessary because in about 26 per cent of cases there is a positive history of bacillary or amœbic dysentery within a period of five years. The sigmoidoscopic examination is usually conclusive for diagnosis and it may be stated as a general rule that the rectum and the sigmoid are never free from the characteristic ulceration. In each case, provided there is no bleeding, further information may be obtained by skiagraphy after an opaque enema.

Sigmoidoscopy.—A careful digital examination is always necessary before instrumentation. Much valuable information is obtained with regard to the condition of the sphincters, the calibre of the lumen, and degree of severity of pain. No violence is permissible and it is always important to keep in mind the friability of the mucosa, owing to its inflamed condition and its liability to hæmorrhage. No local anæsthesia is generally necessary and no special preparation other than a saline enema on the previous night is called for. A sigmoidoscope with a smaller calibre is preferable as in the majority of cases there is some narrowing of the lumen.

TABLE III

Analysis of sigmoidoscopy

Lesions	Percentage
Mucosal thickening and congestion ..	17
Miliary ulcers (moth-eaten) ..	38
Large ulcers with grey base ..	6
Ulcers with gelatinous matter ..	6
Multiple minute bleeding points ..	7
Red granular polyps ..	7
Scars of healed ulcers ..	7
Narrowing of lumen: stenosis ..	6
Fissures ..	2
Fistulae ..	2

The sigmoidoscopic appearance of these ulcers and their different stages have already been described. A differential diagnosis, however, must be made from amœbic ulceration.

During the early stages of the disease, spasticity of the gut was usual; the descending colon (in 35 per cent) and the ascending colon (in 31 per cent) were almost equally involved. In 10

TABLE IV
Differentiation from amœbic ulceration

	Amœbic ulcers	Ulcerative colitis
Nodules	Over crests of transverse folds.	Miliary granules, so-called 'polyps'.
Ulcers	'Button-hole' undermined and shaggy.	Pin-head and pock-like moth-eaten appearance.
Scars	Oval or rounded central pigmentation.	Pock-like.
Rectal valves and folds	Some thickening but folds present.	Obliteration of the valves, œdema of mucosa.
Scrapings	Viscid gelatinous.	Frangible and bleeding.

Sterile swabs and culture of scrapings.—These procedures are carried out as routine measures and have already been described.

X-ray examinations and opaque enemas.—Skiagraphy should follow sigmoidoscopy; a barium meal is usually given in order to investigate the condition of the gastro-intestinal tract. From a radiological survey of our cases in this series, we find that some abnormality of the duodenal cap is present in 37 per cent, a 5-hour residue in the stomach in 28 per cent and other gastric anomalies in about 5 per cent of the total number of cases. An explanation of the gastric symptoms is thus readily obtained, the gastric residue is due either to pyloro-spasm or to atony. There was only one case of duodenal ulcer, the remainder came under the heading of duodenitis (plate VIII, figure 10).

per cent of cases, there was hypermotility associated with diarrhœa. The descending colon appears to be more liable to stenosis with permanent narrowing of the lumen (plate VII, figure 11). Dilatation of the ascending colon was present in 18 per cent and of the descending colon in 5 per cent. A 48-hour residue was obtained in 28 per cent, representing chronic cases with ulceration and narrowing of the lumen (plate VII, figure 12). It is evident that skiagraphy will reveal the extent of the disease, site of stenosis, fixity of the gut and loss of haustration (plate VII, figure 13). Some malformation of the cœcal base is also an important feature.

Clinical features

Incidence of sex.—The percentage ratio between males and females was 72 : 28.

Incidence of age.—Chronic ulcerative colitis is chiefly a disease of the second and third decades of life.

Early stage.—The clinical features in the early stages are unfortunately not very definite and the condition is generally diagnosed as dyspepsia, 'tropical neurasthenia', chronic constipation, recurrent diarrhœa, or even dysentery. But when the signs and symptoms are well marked, diarrhœa, precipitate motions, with discharge of mucus and blood are prominent features. In spite of periodic remissions vague digestive symptoms are generally complained of. The incidence of gastric symptoms is easily explained by a reference to the tables on radiological analysis. The rarity of the presence of peptic ulceration is worthy of note. In general, abdominal cramps, rectal pain and discomfort, tenesmus and urgency may make life unbearable. Pyrexia is present at some stage or other in nearly half the cases. The pulse is an important guide to prognosis for, if it exceeds 120 per minute, it is a serious omen (Bell, 1936). In this review, we are not considering the acute type of ulcerative colitis which quickly leads to a fatal termination.

Periods of remission.—These are very variable but each succeeding attack becomes more acute than the last one and brings about severe prostration and loss of weight. Many of these cases are considered to be 'tropical neurasthenia', because the condition is frequently ushered in by serious emotional disturbances. Relapses are

TABLE V
Analysis of 120 cases of colitis: a radiological survey

Stomach—			
5-hour residue	28		
Other anomalies	5		
Duodenum abnormalities of cap ..	37		
Appendix—			
Visualized	33		
Residue	3		
Cæcum abnormalities	17		
Ptois	20		

The appendix was visualized in 33 per cent of cases while a residue was obtained in 3 per cent only. From the study of these figures it appears that gross lesions did not extend, at the earlier stages, throughout the entire length of the large gut. Abnormalities of the cæcum were present in 17 per cent.

TABLE VI
Analysis of the radiological appearance of the colon

	Spasticity	Dilatation and stasis
Ascending colon	31	18
Transverse colon	5	5
Descending colon	35	5
Hypermotility	10	..
Irregular filling	20	..
48-hour residue	28	..

common after infections of the upper respiratory tract.

Intestinal hæmorrhage.—The incidence of hæmorrhage is also variable. In one attack it may be alarming and in the succeeding ones there may be no bleeding at all. The blood may be bright red and may come with frequent discharge of mucus, but melæna is not uncommon when the cæcum and the proximal part of the colon are involved.

Clinical types.—It is not always possible to divide chronic ulcerative colitis into clinical types but it would be of some practical use to consider them as belonging to one or other of the following groups: (i) infective, (ii) allergic, (iii) avitaminotic, and (iv) neurasthenic. These will be referred to in the next section.

Treatment

It has to be admitted that there is no specific for this condition; the treatment is generally protracted and somewhat onerous, a careful dietetic regime having to be maintained.

I. *General and medical treatment.*—As early cases are seldom seen by the surgeon, only chronic and moderately serious cases are included under this group. The time of strenuous treatment is at the early stages before the colon is converted into a physiologically inefficient organ owing to fibrosis and stenosis (Goodall, 1936).

1. *Rest in bed.*—This is very important for maintenance of strength and control of fever. Exercise or activity usually increases the tenesmus and frequency of motions. *Postural treatment.* In the more serious cases, frequency of motions is distressingly increased even by the erect posture alone. Appreciable relief is quickly obtained by beginning the treatment in the recumbent position. In this position the force of gravity, which increases the sag of the organs and the strain on the body as a whole when in the upright posture, is practically eliminated. For this purpose both the 'hyperextension position' with dorsal decubitus and pillows under the knees, and 'the face prone' position are recommended.

2. *Diet.*—By general consensus of opinion a low-residue diet is best, but it is important to remember two fundamental desiderata. Firstly, the diet should be made up of adequate calories for maintenance of good health and body-weight, and, secondly, it must contain the necessary vitamins. Many patients go down hill because the diet is too restricted and monotonous. In a case of moderate severity it is best to begin with a modified Sippy treatment with addition of Benger's food and suitable extractives. A more generous diet may be quickly allowed, provided there is no bleeding or abdominal cramps.

3. *Administration of vitamins.*—There is reason to believe that avitaminosis is an important factor in the ætiology of this disease. (i) Ascorbic acid (vitamin C) has an excellent styptic effect in hæmorrhages of ulcerative colitis.

It is given in the form of 'Cantan' (Bayer) either intravenously or intramuscularly in daily doses of 150 mgm., until there is only one motion free from blood and pus (Hetenyi, 1935). In less urgent cases the drug may be given orally, the usual dose being one tablet three times daily. (ii) *Vitamin-B complex.* It is as yet difficult to indicate the precise effect of vitamin-B complex on ulcerative colitis. In the form of 'marmite' it has been found to be a valuable adjunct in the treatment of this disease. (iii) *Vitamins A and D.* We cannot say that cod-liver oil by mouth has been beneficial but rectal instillation has been attended with gratifying results and will be referred to again.

4. *Treatment of allergy.*—There is little doubt that in a number of cases a definite history of allergy is obtained, but it is not possible to state at present whether the allergy is due to a particular protein or some unknown amino-acids as the result of incomplete digestion. In this group 'Torantil' (Bayer) is worthy of trial as very gratifying results are not infrequently obtained. One ampoule of 'Torantil' is injected intramuscularly twice a week; one course comprises five injections. This is followed by a course of oral treatment consisting of one pellet before each principal meal for one week. The patient should be watched carefully as in some cases, which are impossible to predict, the symptoms may be definitely aggravated. In one case, after the ingestion of two pellets, serious bleeding was definitely stopped.

5. *Mental tranquillity.*—The restoration of mental peace after serious emotional disturbance is not easily achieved. In these cases it may be necessary to administer sedatives. Elimination of mental worries tends to rapid improvement in one group of cases which may be called the neurasthenic type. Vitamin-B complex is usually beneficial in this type of case. Psychotherapy may be needed in a serious case of nervous breakdown and severe mental depression.

6. *Vaccines and sera.*—Bargen (1935) and Buie (1937) report excellent results with auto-vaccines and specially prepared sera, but we have not been very fortunate in our results. 'Pron-tosil' (Bayer), which has been so successful in our hands (Ray, Alam and Ghose, 1938) in

various streptococcal infections, does not seem to be efficacious; neither have anti-streptococcal sera of reputable makes proved of any greater value. Auto-vaccines in a few cases have been beneficial, affording some amelioration of symptoms.

7. *Drugs*.—There are no specific drugs, but a few need mention for purposes of symptomatic treatment:—

(i) *Buffered citrate therapy* (Montague, 1934). Success has been claimed with this method of treatment and it is ascribed to an improvement of acid-base balance of blood, lessened tendency to alimentary capillary stasis and venous thrombosis, and improved tissue resistance to general infection. Schultz's solution is used for intravenous injection. It consists of a combination of sodium citrate and sodium chloride buffered with a salt which raises the concentration of the solution somewhat higher than that of normal blood. The initial dose consists of 10 c.cm. This is doubled after 24 hours and continued on alternate days.

(ii) *Lactose*.—It is probably not quite correct to include lactose among the drugs, but it is particularly valuable in cases where flatulence and intestinal fermentation are troublesome, and it may be used in place of sugar and glucose. In chronic constipation, it is useful as a mild laxative.

(iii) *Plantago ovata*.—It is known in the vernacular as 'ispaghula' or 'isabgul' and is a well-known and popular remedy in chronic dysentery, on account of its emollient and demulcent effect. The seeds are thoroughly cleaned free from sand and grit with which they are mixed. Two to four heaped dessertspoonfuls are mixed with a little sugar and shaken up in a cupful of water and the mixture is then swallowed. The drug has no bactericidal action and its effect appears to be entirely mechanical. The seeds after ingestion become uniformly mixed with the intestinal contents so that they are spread uniformly over the entire surface of the mucous membrane. The irritated or ulcerated areas of the intestinal mucosa are soothed by the demulcent action of the mucilage, which is not acted upon by the intestinal juices. It thus covers the surface of these ulcers protecting them from further irritation. The drug is tasteless and in chronic constipation it produces a laxative action similar to that of agar (Chopra, 1936).

(iv) *Kaolin*.—Kaolin has been used for its adsorptive effect on the bacteria and their toxins and for the production of formed stools where looseness of the bowel is a predominant symptom. In a severe case of ulcerative colitis the entire colon, as a result of chronic inflammation and destruction of the epithelium, has lost so much of its absorptive power that very large amounts of the drug would be required, endangering the removal of necessary vitamins by adsorption. It, therefore, seems probable that

the potential dangers offset the potential value of this medication (Emery, 1937).

(v) *Opiates*.—In spite of the introduction of numerous substitution products it is doubtful if the action of opium can ever be excelled by any other drug for the induction of sleep, control of diarrhoea and increased frequency of motions, and the relief of abdominal pain. Tincture of opium in five to ten minim doses is invaluable for prompt relief. Compound tincture of camphor, in one drachm doses, is also useful. It is important, however, to discontinue the drug as soon as the desired therapeutic effects have been obtained.

(vi) *Maintenance of water balance*.—In cases of diarrhoea and vomiting it is imperative to maintain an adequate water balance, and for this purpose, when necessary, solutions of glucose (25 c.cm. of 25 per cent solution) should be administered intravenously, and normal saline solution subcutaneously.

(vii) *Calcium and parathyroid*.—Prolonged administration of calcium lactate (5 grains) and parathyroid extract (1/20 grain) appears to be beneficial in a number of cases.

II. *Local and surgical treatment*.—Surgical measures may have to be undertaken for palliation of symptoms or treatment of complications.

(i) *Transfusion of blood*.—A high degree of anaemia is not infrequent in ulcerative colitis and is due to continuous loss of small quantities of blood in the faeces. In these cases a small transfusion (200 c.cm.) twice weekly for three or four weeks may be carried out with benefit. On rare occasions transfusion of blood may be necessary as a life-saving measure. With neo-haemoplastin (Parke, Davis and Co.) excellent results are generally obtained, but failures are not infrequent, whereas repeated transfusions of blood may be successful. In massive hæmorrhage morphine is indispensable as in duodenal hæmorrhage.

(ii) *Medicated enemata*.—Since the disease affects all the coats of the large gut, the use of medicated enemata may be rightly regarded as illogical. Stronger antiseptics cannot possibly reach the deep-seated diseased areas and, on the contrary, may aggravate the patient's condition by further devitalizing the superficial ulcers and lead to delay in healing. Nothing can supersede a normal saline enema in these cases. Local instillation of cod-liver oil has been found to be beneficial. It was first tried by us empirically, as we were impressed with its encouraging results in some intractable ulcers of the skin. At first half an ounce of cod-liver oil was injected at night slowly with a rubber catheter, but in the majority of cases it was promptly rejected. In about a week's time retention of the oil was found to be fairly satisfactory. A better method consists of giving a 40 per cent emulsion of cod-liver oil with gum acacia. The emulsion is instilled two to four times a day in doses of two to four ounces with a gradual increase up to eight ounces (Spiegel, 1937). Marked improvement

is not usually noticed before three months. A 60 per cent suppository of cod-liver oil may also be used. The vitamin treatment, when successful, produces a brilliant result.

(iii) *Operative procedures.*—The object of the usual operative procedures is to give rest to the diseased parts by diverting the faeces through an artificial anus.

(a) *Appendicostomy.*—Although this operation is still recommended by many for the purpose of lavage, the result, in our opinion, can only be described as unsatisfactory.

(b) *Cæcostomy.*—This operation was performed with much greater enthusiasm in the past with the laudable object of short-circuiting the faecal contents and for providing prolonged rest to the diseased colon. The results do not, however, justify this operation. When the colon is extensively diseased, after a prolonged period of rest it is converted into such a mass of fibrosis that functionally it becomes useless and the cæcostomy remains as a permanent token of futile surgical interference.

(c) *Left colostomy.*—This may have to be performed either as a life-saving measure in case of intestinal obstruction associated with rectal stricture or as a palliative measure for extensive fistulae and pelvic cellulitis. Unfortunately this may remain a permanent artificial anus.

(d) *Ileostomy.*—In the past ileostomy was advocated as a temporizing measure instead of colostomy, but usually the patient succumbed soon after (Lardennois, 1936).

(e) *Short-circuiting operations.*—Theoretically anastomosis between the ileum and the lower colon has been advocated, with or without excision of the remaining part of the large intestine. This operation is not a practical proposition for the simple reason that the rectum and the sigmoid are the parts which suffer most. Besides, few patients would be able to survive the severity of such a major operation.

(f) *Surgery of complications.*—Of the complications most commonly complained of, fistula-in-ano, fissure, and so-called 'piles' need mention. The golden rule is not to interfere unless there is some definite indication.

Results of operative treatment.—The results of operative treatment have been uniformly unsatisfactory; moreover, the simplest surgical interference entails a high rate of mortality (25 to 40 per cent). Unfortunately, the formation of an artificial anus is indicated in the neglected cases complicated by stenosis of the rectum or the sigmoid colon, perineal cellulitis or multiple fistulae. Of the rare complications which require operative treatment, may be mentioned intestinal obstruction and perforation which are, however, usually attended with a fatal result.

Prognosis

At best, the prognosis is, if anything, better than in the past. In about 50 per cent of cases definite improvement takes place but the treatment must be prolonged and laborious. It is yet too early to say if recurrence can be prevented.

In the more chronic cases, even if the ulcers are healed, proneness to diarrhoea and mucous discharge tends to persist owing to gross damage to an extensive area of the large intestine and consequent impairment of its physiological function of absorption of fluid. Some peristaltic disturbance persists also owing either to the mechanical cause of widespread fibrosis or impairment of the neuro-muscular mechanism.

Summary

This review of chronic ulcerative colitis is based on the clinical study of 120 cases with special reference to diagnosis, pathological findings, radiological analysis and treatment.

1. Chronic ulcerative colitis may be regarded as a disease of the large intestines during the second and third decades of life with characteristic clinical and pathological features but without any specific bacteriological infection.

2. It has not been possible to determine any single aetiological factor for ulcerative colitis. It is possible that many factors combine to produce devitalization of the mucous membrane of the large intestine leading to chronic ulceration.

3. Of the aetiological factors, avitaminosis, allergy, faulty body mechanics, emotional disturbances, streptococcal infection, and dysentery require special consideration.

4. In diagnosis, the sigmoidoscopic appearances are usually conclusive. In early cases, several stages may be described for convenience. In the *first stage*, the mucous membrane of the rectum and the sigmoid shows signs of hyperaemia and inflammation. In the *second stage*, the cedematous mucosa is studded with greyish-yellow granules representing minute necrotic foci. In the *third or active stage* there is the typical moth-eaten appearance owing to the breaking down of these granules. The *healing stage* presents multiple indolent ulcers and scars, while in the more chronic stage multiple vascular granular polyps are seldom absent. In another group of cases, large chronic ulcers are found, which show little sign of healing owing to superinfection of secondary infection.

5. At an early stage, when no ulcers are present, the microscopic picture consists of capillary dilatation, diapedesis, and hæmorrhage. The granular stage corresponds to minute necrotic foci under the mucous membrane with occlusion or thrombosis of the deeper vessels. Multiple small ulcers are next seen in the moth-eaten granular mucosa. Within the deeper tissues there are scattered necrotic areas containing hyaline-like material in various stages of fibrosis.

6. In the analysis of our cases we have not been able to point to any particular organism as the exciting cause. The bacterial examination of faeces showed an incidence of only 4 per cent for *E. histolytica* and 3 per cent for bacillary dysentery. The non-dysenteric character of chronic ulcerative colitis is therefore clearly indicated. *Streptococcus faecalis* was isolated in only 4 per cent of cases. We have included

Ps. pyocyanea, *Bact. morgani*, *B. carolinus* and *B. meta-alkaligenes* in this investigation, because they appear to be incriminatory. The analysis of scrapings of ulcers of the rectum and the sigmoid also point to the non-specific character of these ulcers. Culture of blood was found to be uniformly negative.

7. From a radiological survey of our cases in this series some abnormality of the duodenal cap was present in 37 per cent, a 5-hour residue in the stomach in 28 per cent and other gastric anomalies in 5 per cent. The gastric residue is due either to pylorospasm or to atony. There was only one case of duodenal ulcer, the remainder came under the heading of duodenitis. The appendix was visualized in 33 per cent but a residue was obtained in only 3 per cent. Abnormalities of the caecum were present in 17 per cent. At an early stage of the disease spasticity of the gut was usual; the descending colon (35 per cent) and the ascending colon (31 per cent) were almost equally involved. Hypermotility was seen in 10 per cent and was associated with diarrhoea. The lower gut appears to be more liable to stenosis, while dilatation of the ascending colon was present in 18 per cent and of the descending colon in 5 per cent. A 48-hour residue was obtained in 28 per cent, representing chronic cases with ulceration and narrowing of the lumen.

8. The percentage ratio between males and females was found to be 72 : 28. The signs and symptoms in the early stage are not very definite, but when well marked, diarrhoea, precipitate motions, discharge of blood and mucus are prominent features. The periods of remission are very variable, but each succeeding attack becomes more acute than the last one and brings about severe prostration and loss of weight. Clinically, four types may be differentiated, viz, (i) infective, (ii) allergic, (iii) associated with avitaminosis, and (iv) neurasthenic.

9. There is no specific for this condition and treatment is generally protracted. A somewhat onerous and careful dietetic regime has to be maintained. Rest in bed with postural treatment is always important for maintenance of strength, control of fever and diminution of tenesmus and frequency of motions. A low-residue diet is recommended, but it must be made up of adequate calories and it must contain the necessary vitamins. Ascorbic acid (vitamin C) has an excellent styptic effect in rectal hæmorrhage. Vitamin-B complex has a beneficial effect, but it is as yet difficult to indicate the rôle it plays. There is little doubt that allergy, when present, is due to a particular protein or some unknown amino-acid resulting from incomplete digestion. In this group of cases 'Torantil' (Bayer) is worthy of trial. Elimination of mental worries is an important factor in recovery. Vaccines and sera do not appear to have any definite effect. Of the drugs, lactose and *Plantago ovata* (isabgul) are useful. Buffered citrate therapy and kaolin have also

their advocates. In spite of the introduction of numerous substitution products, it is doubtful if the action of opium can ever be excelled by any other drug for the induction of sleep, control of diarrhoea, and relief of abdominal pain in a really severe case.

10. Surgical measures may have to be undertaken for palliation of symptoms and complications. Transfusion of blood may be required either for severe anaemia or as a life-saving measure. Medicated enemata do not appear to be useful because the disease affects all the coats of the large gut. Rectal instillation of cod-liver oil or emulsion has been found to be beneficial. The object of the usual operative procedures is to give rest to the diseased parts by diverting the faeces through an artificial anus. Operative measures, such as appendicostomy, ileostomy and short-circuiting operations, are now seldom resorted to. Of the complications most commonly complained of, fistula-in-ano, fissure and so-called 'piles' need mention. The golden rule is not to interfere in these cases unless there is a definite indication.

11. At best the prognosis is, if anything, better than before. In about 50 per cent of cases definite improvement takes place with clinical cure but the treatment must be prolonged and laborious. It is yet too early to say if recurrence can be prevented. In the more chronic cases, even if the ulcers are healed, proneness to diarrhoea and mucous discharge tends to persist, owing to gross damage to an extensive area of the large gut, with consequent impairment of its physiological function of absorption of fluid and peristalsis.

Acknowledgments

In conclusion, we wish to acknowledge our indebtedness to our many colleagues for their valuable help. To Major C. L. Pasricha, I.M.S., our best thanks are due for the pertinent laboratory data, and to Lieut.-Col. J. A. Shorten, I.M.S. (retd.), we are indebted for the skiagraphy. We also wish to acknowledge our indebtedness to Prof. C. C. Bose and Dr. D. N. Bannerji, M.D. (Berlin), of the Carmichael Medical College and their colleagues for the pathological investigation. Our best thanks are also due to our house staffs and, in particular, to Dr. M. P. Talukdar, registrar of the Carmichael Hospital for Tropical Diseases.

ABERRANT PANCREATIC TISSUE IN THE ALIMENTARY TRACT

By M. M. CRUICKSHANK

LIEUTENANT-COLONEL, I.M.S.

Madras

THOUGH the presence of pancreatic tissue in the alimentary tract is still considered an infrequent anomaly, yet over 350 cases have been reported in the literature, since Klob in 1859 reported the first case. Of the heterotopias found in the alimentary tract the accessory pancreas is the commonest.

The most common sites are the stomach and duodenum and the most frequent pre-operative diagnosis is either gastric or duodenal ulcer. This is what is to be expected, when one considers the development of the pancreas.

'It is probable that accessory pancreatic tissue is formed from lateral budding of the rudimentary pancreatic ducts as they penetrate the intestinal wall, the mass of pancreatic tissue thus formed being snared off and carried by the longitudinal growth of the intestine either upward or downward' (Warthin). That such irregular budding does occur is evidenced by the finding of such buds in close proximity to the duodenal papillæ, especially the lesser.

Similarly, the presence of pancreatic buds in the gall bladder is explained by the lengthening of the common bile duct, as the gall bladder developed.

On the other hand, acquired heterotopias do occur, in the same way as epithelial heterotopias of the alimentary tract arise during the healing process which follows a chronic inflammatory lesion, where ulceration and loss of tissue have occurred. As an example of this, one may cite

those instances where the healing epithelium of the stomach takes on the morphological features of small gut.

The significance or importance of the presence of aberrant pancreatic tissue lies, of course, in the frequency with which it is mistaken for gastric conditions, more especially, if mistaken for neoplastic growths.

The pancreatic nodule in the gut may be the exciting cause of an intussusception; it may cause pyloric stenosis or acute intestinal obstruction; it may be the seat of an acute or chronic inflammation or of a carcinoma.

Pathologically two types are described, the aberrant pancreatic nodule and the annular pancreas.

The former is a much more common type and is the form which gives rise to difficulties in diagnosis and in many instances goes unrecognized until encountered during the course of some abdominal operation.

The rarer annular pancreas encircles the second portion of the duodenum and gives rise to constriction of that portion.

This form has definite clinical importance in that it may give rise to all the signs and symptoms of high intestinal obstruction. Whereas the nodular type is discovered usually at operation, the annular type, unfortunately, is usually a post-mortem finding.

The relation of carcinoid tumours of the appendix and small intestine to pancreatic rests has been a subject for much discussion. Some pathologists have stated that both adenomyomas and carcinoids arise in pancreatic rests and that carcinoids were pancreatic rests in which only the islet cells of Langerhans appeared. Masson and others have, however, shown that no such relationship exists and that carcinoids arise from chromaffin or argentaffin cells in the crypts of Lieberkühn. Moreover, carcinoids are found most frequently in the appendix, while pancreatic tissue has never apparently been found in the large bowel.

Report of a case

A Hindu, male, aged 25 years, was admitted into hospital, complaining of pain in the upper region of the abdomen, which had lasted off and on for over two years.

Family history.—Nothing relevant.

Previous illnesses.—Nothing relevant.

History of present illness.—Has suffered from attacks of epigastric pain for two years. These attacks last anything from three to ten days and are followed by free intervals varying from four to eight weeks, but latterly the intervals have shortened to one week. The pain comes on about half an hour after taking food and lasts for about three to four weeks. The pain is relieved by vomiting which is spontaneous, but is on occasions induced. The vomit has occasionally been streaked with blood and the patient has, so he states, passed dark tarry-looking motions. Appetite has

THE HEART IN ANÆMIA

By GEORGE R. McROBERT, M.D.

LIEUTENANT-COLONEL, I.M.S.

and

D. GOVINDA REDDY, M.D.

(General Hospital, Madras)

In dealing with a patient with a damaged heart the physician must not only take into consideration the state of the myocardium, valves and vessels, but must carefully investigate the oxygen-carrying power of the blood.

In India, particularly, stress has to be laid on this aspect of cardio-vascular pathology and therapeutics. Again and again, it is found that the child or young person with a mitral stenosis and dyspnoea responds well to large doses of iron,

(Continued from previous page)

always been and still is good, but he is afraid to eat on account of the pain. Bowels tend to be constipated. There is no history of jaundice. Patient has been losing weight considerably of late.

Condition on admission: General condition.—Good. A healthy looking man, rather thin, but with no abnormalities anywhere except his stomach complaint.

Local condition: Abdomen.—Soft: tenderness is elicited over the upper part of the right rectus. Visible peristalsis is present.

Fractional test meal.—High acid curves, with an abrupt rise suggestive of duodenal ulcer.

No blood or mucus in any specimen.

Starch present in all specimens.

Barium meal.—Screening showed flattening and spasm of the duodenal cap; stomach of normal outline; stomach still held a small amount of barium in the 5th hour picture.

Diagnosis.—Duodenal ulcer.

Treatment.—24th May, 1937. Operation under spinal anaesthesia. Ethocain 16 c.c. of a 1 per cent sol. Abdomen opened through a supra-umbilical paramedian incision. An indurated mass of the size of a golf ball was found at the pyloric end of stomach and over the first part of duodenum. This inflammatory mass was intimately adherent to the under surface of the liver. The transverse mesocolon was so short that the colon lay across the vertebral column, rendering the usual posterior no-loop gastro-jejunostomy impossible. A posterior gastro-jejunostomy, however, was carried out by bringing the jejunum in a four to six inches loop over the fixed transverse colon. The appendix was abnormally long and was removed. On the anti-mesenteric border of the jejunum in the region where the anastomosis had to be made was a mass about 2½ inches long by ¾ inch broad. The mass, lying under the peritoneal coat, was of a light brownish colour, and of a mammillated appearance. As far as the gross appearance went, the mass suggested a lipoma, but the site suggested aberrant pancreatic tissue. In making the stoma, the tumour was removed and sent to the pathologist who reported 'a submucous adenoma in which are seen areas of glandular tissue, resembling that of pancreas', plate VIII, figures 1 and 2 (p. 71). A second report followed after many serial sections had been made and examined: it read as follows:—'Though many sections have been made and examined, only one section shows a single islet of Langerhans, thus confirming the first report'.

The patient made an uneventful recovery and was discharged four weeks after admission.

and that when the anæmia has been removed the heart again becomes able to carry on its duties without the production of breathlessness. A number of patients, indeed, who come to hospital complaining of what at first sight seems to be cardiac disease, are but subjects of advanced anæmia.

In the course of a series of investigations on cases of anæmia we have had a number of serial 2-metre telerradiographs made at the Barnard Institute, Madras, and have been struck by the decrease in the size of the heart shadow in treated cases of severe anæmia. The most striking is that cited below:—

Case 1.—A., male, aged 14 years, Hindu, non-vegetarian, carpenter, reported at hospital on 10th February, 1938, complaining of weakness, precordial

Fig. 1.

Fig. 2.

HEART MEASUREMENTS. CASE 1

	Average	On admis- sion, 10-2-38	After treatment, 13-3-38
Long diameter	.. 14.0 cm.	15.0	13.0
Transverse "	.. 10.1 "	17.2	12.9
Basal "	.. 10.7 "	14.0	9.0
Cardio-thoracic ratio	..	0.71	0.54

distress and breathlessness. The condition had set in gradually and he had not felt fit for four years. The patient was extremely pale, the body and face appeared 'puffy' and there was œdema of the feet with pitting on pressure. The conjunctivæ and nails were extremely pale, but there was no koilonychia nor was the tongue sore. The skin and the angles of the mouth appeared healthy, and careful investigation of the nervous system revealed nothing abnormal—certainly nothing suggestive of beri-beri. The urine was normal. On examination of the cardio-vascular system there was bulging of the precordium with obvious diffuse systolic heaving. The apex beat was visible, diffuse and easily palpable in the 6th intercostal space 1½ inches external to the midclavicular line. The jugulars pulsated strongly as did also the epigastrium. No thrill was felt on palpation. On auscultation, the heart sounds were loud and very easily heard; the first sound at the apex and tricuspid areas was followed by a blowing murmur not well conducted, whilst at the base of the heart there was loud systolic bruit. There was no history of rheumatism.

Tonsils normal.

Respiratory system—normal.

Spleen not palpable.

Liver palpable half an inch below costal margin; soft and slightly tender.

Examination of the blood revealed a severe microcytic anaemia with anisocytosis and poikilocytosis, but no nucleated red cells. No parasites were seen.

Faeces—numerous hookworm ova.

Van den Bergh—direct negative; indirect positive.

Icterus index 15 units.

Wassermann and Kahn reactions—negative.

Preliminary screening revealed an unusually voluminous heart, generally enlarged in all its diameters, but especially to the right.

The cardio-thoracic ratio was 0.71.

The reduced tracing of a 2-metre teloradiograph is shown in figure 1. Figure 3 indicates the condition of the blood on admission with progressive improvement.

It was decided to treat the boy as a pure case of hookworm anaemia and in order to eliminate the rest factor, he was told not to recline in bed except when sleeping, but to move about the ward and verandah. He was given ordinary ward diet, without extras such as fruit and milk or vitamin preparations.

Ninety grains of iron and ammonium citrate were given daily and the improvement can be seen in figure 3. De-worming was postponed until the haemoglobin had increased to 40 per cent when 1 c.cm. of oil of chenopodium and

Fig. 3.—Showing response to iron and ammonium citrate, 90 grains daily, with anti-helminthic treatment (A-H). The size of the heart was reduced practically to normal limits (figure 2); the precordial pulsations and the loud systolic murmurs completely disappeared.

The boy who had co-operated well in the investigations left our wards an apparently healthy, cheerful and vigorous young specimen of humanity, having gained 20 pounds in weight, with no ova in his faeces and with a cardio-thoracic ratio of 0.54.

Another similar case is reported:—

Case 2.—C., aged 45 years, admitted for giddiness and loss of breath on exertion of six months' duration. The clinical and pathological findings were practically identical with those already quoted. Normal urine.

Hookworm ova ++.

Wassermann reaction—negative.

Van den Bergh—indirect positive, faint.

Icterus index 8 units.

Blood: Severe microcytic anaemia.

Similar treatment without rest and with ward diet was given. Iron and ammonium citrate, grs. 90 per

day, were prescribed. His red cell count reached almost normal figures in 45 days on iron alone. Two courses of worm treatment, as in case 1, were given (figure 4).

The cardiac outline on admission is shown in figure 5.

He was discharged feeling fit and strong, having put on 10 lb. in weight and with none of the systolic murmurs present on admission. (Size of heart, figure 6.)

Fig. 4.—Showing response to iron and ammonium citrate, 90 grains daily, with anti-helminthic treatment (A-H).

Fig. 5.

Fig. 6.

HEART MEASUREMENTS. CASE 2

	'Normal'	On admission, 14-4-38	After treatment, 14-5-38
Long diameter	.. 14.0 cm.	16.2	14.7
Transverse "	.. 10.1 "	17.0	13.7
Basal "	.. 10.7 "	13.5	10.6
Cardio-thoracic ratio	..	0.68	0.56

Such cases serve to emphasize the great efficacy of simple iron therapeutics in anaemia in India and the importance of eliminating the anaemia factor before making a diagnosis of cardiac disease.

We have to thank Dr. M. J. Santhanakrishna Pillai, Medical Superintendent, Barnard Institute of Radiology, for the teloradiographs and the measurements.

THE LOCAL PROVISION OF SPLINTS AND TACKLE FOR FRACTURES AND JOINT INFECTIONS IN INDIA

By F. H. WHYTE, M.B., M.Ch., F.R.C.S.I.

MAJOR, I.M.S.

Civil Surgeon, Ranchi, Bihar

THE Inspector-General of Civil Hospitals, Bihar, Colonel H. Stott, having kindly suggested that I should publish an account of how we prepare most of our splints for the Sadr Hospital, Ranchi, I shall endeavour to give a summary of the procedure we use here, with comments on the general situation in India, as influenced by the warm and moist climate and the shortage of funds in most of our hospitals, which shortage is inevitable in a tropical country with almost 400,000,000 inhabitants. The treatment of fractures and joint diseases occupies a very prominent part of surgical practice in this continent and tuberculosis of the bones in children, in particular, must give us all very considerable concern.

In comparison with the non-tropical and wealthier countries, which supply almost all the textbooks on orthopaedic surgery, in India, climate and expense require very definite consideration.

No one could read modern books, such as Böhler's *Treatment of Fractures*, or endeavour to practice their methods without the greatest admiration, but unfortunately the cost of usually purchased splints, the delay in obtaining them in correct sizes, and the unsuitability of extensive plasters in India, to my mind render the local manufacture of splints and fracture tackle a necessity and the elimination of most of the extensive plasters by metal frames, essential to the comfort and welfare of our patients.

It does not require much observation to see that to wear plaster jackets or spicas for fractures or tuberculosis of the spine and hip is a very severe trial, particularly in the hot weather. They are unsatisfactory as a rule to all concerned. They are often simply intolerable in the hot weather, damp and heavy with perspiration, difficult to keep clean and hard, and consequently they require repeated applications. They are depressing to the patient's health and resistance. Though occasionally one has seen satisfactory results, under good circumstances, from plasters for tuberculous lesions and fractures of the spine and hip—I now consider their only indications are fractures occurring early in the cold season. Large plasters, even in the so-called 'cold' weather, can depress the patient's health and lower his resistance against tuberculous disease.

Early last cold weather, assisted by my staff, I applied in hospital a spica for a typical tuberculous hip in a child of nine years, just showing x-ray changes. The child's progress in his own home was satisfactory for some time but towards

the end of the cold season, loss of weight with general misery and the development of a cold abscess, indicated very definite depression of resistance. We changed over to a double Thomas' hip splint and, though the hot season was against the child, the rapid improvement was noticed by all. Personally, I cannot remember seeing a cold abscess, which was on the point of rupture, clear up so quickly, or a miserable and wasted child, become cheerful and fat so rapidly.

Other arguments against these extensive plasters are the difficulty in fitting very heavy patients, the loss of time and expense of repeated applications, the slow set in the monsoon and the too rapid set in the dry heat, the difficulty with profuse discharging sinuses or wounds, the relatives do not like them and often remove them when the patient is sent home, or the patients themselves injure them, even when in hospital. Personally, I do not blame the relatives or patients for considering an extensive plaster often worse than the fracture or disease. The patient's skin in a hot climate does not stand up to pressure, if not regularly treated, in anything like the way it does in cold countries. It must be a serious mistake practically to eliminate the functions of half the surface area of a patient's skin for months in a hot climate.

It might appear a formidable proposition to undertake the manufacture and accurate fitting of splints for a district hospital and I might add that some success only leads to expansion of work in this department, but, with a reasonable scheme to begin with, the procedure is simple and the time and money saved in shorter hospitalization, easier nursing and diminished dressings, etc., are very obvious to all. If it pays to treat fractures well, it must also pay to treat tuberculous joints well.

It is astonishing what can be done if one tries and to encourage other hospitals to take up the manufacture of some of their own splints; I append a photograph of most of our equipment and give some of the features we have found essential to make it really easy and cheap. We are fortunate in having a particularly useful *mistri*, but supervision is constantly necessary.

Equipment

The tools, etc., required as follows :—

A forge—a hand-driven Buffalo forge is excellent. An anvil, tongs for dressing the fire, steel cutting chisels, steel punches, a file, strong pliers, a heavy hammer for cold riveting, a tape measure and chalk, strong scissors for cutting tin sheet and a bucket for cold water. We obtained our forge through the helpful agency of a grateful motor mechanic patient, who got it for us, 50 per cent cost price, i.e., Rs. 25. He also supplied an old Ford engine and two feet of heavy iron girder as anvils, gratis. Most of the other equipment mentioned, you can usually find in hospital or bazar.

A *mistri*—most hospitals have one on the staff. A preliminary hour's demonstration was sufficient to give him a good start in his new art. We built our first splints under the cook-house verandah one wet morning. We now use a somewhat cramped godown.

These *mistris* are extraordinarily handy, when once they clearly get the idea of what is required. Incidentally I cannot consider the time lost which I spent, in my youth, admiring the local village blacksmith at work, or, a greater privilege still, assisting him beat out a set of horse shoes. Not infrequent visits to the saddler, cobbler or tailor, I am certain, is good ground work, particularly appropriate to anyone who

plaster, pattens for boots, etc. Many other items such as bed rests, cradles for fractures, screens, etc., can be copied from catalogues, as occasion demands. In 1925 I had tonsil dissectors and forceps made in a forge in Waziristan, which I have used ever since. Though not of stainless steel, they serve the purpose in preference to others. A set of transfixion pins was another item of excellent quality made by the local representative of the surgical manufacturer as found in Razmak.

The next step was to visit a conveniently-placed ironmonger's shop. (My assistant surgeon and I selected Messrs. Dutta Brothers, Upper Bazar, Ranchi). We examined the most

intends to use his hands, not only for orthopaedic surgery but also for general surgery. These visits were a great joy to begin with, pleasant memories, and a constant help ever since. It is ridiculous to expect anyone to be able to undertake operative surgery who has only practised with a hammer and chisel on dead bone, or with a needle on lifeless intestine, in the short courses of operative surgery in a medical school.

A series of model splints, usually in sizes suitable for a child of 12, were prepared. These, the *mistri* copied from pictures in catalogues and made from flat wire binding from packing boxes, occasionally using flat iron or round iron rods, galvanized sheeting and iron rivets. Our list includes Thomas' double and single hip splints, simple spinal back splint, Thomas' knee splints, Jones' crabbed splints—arm and leg, Jones' arm-straight splint, walking irons for

suitable flat iron bars, round iron rods, rivets and galvanized tin sheeting. The materials chosen from many were:—

Flat iron rods—1 inch \times 1/8 inch \times 18 feet, costing Re. 1 each

Flat iron rods—3/4 inch \times 1/8 inch \times 18 inches, costing As. 11 each.

Round iron rods—5/16 inch \times 12 feet, costing As. 4-6 each.

Round iron rods—4/16 inch \times 12 feet, costing As. 3 each.

Iron rivets—3/16 inch \times 3/8 inch, costing As. 0-6 per dozen.

Galvanized tin sheeting—6' \times 3' \times 24-gauge Rs. 2-4-0 each.

We settled prices and a prescription form, taking copies for hospital use. On a prescription the adult patient pays Re. 1-0-0 for the iron and rivets to make a double hip splint.

A *mochi* from Dean Brothers, saddlers and boot makers, Ranchi, was called to the hospital

and shown a completed Thomas' hip splint and some others requiring leather work. Prices were fixed, i.e., for covering a Thomas' double hip frame with sheep hide, fitting chrome leather straps and buckles, adult's size, Rs. 4, and for a child's, Rs. 3. (I don't favour padding the rings of Thomas' knee splints for patients under a Balkan frame).

To complete the fracture scheme, it might appear superfluous to add the necessity of having say four to six Balkan frames. These can be made locally from teak wood at very reasonable prices, Rs. 20 or Rs. 15 each. I find a series of 2 inch screw nails at intervals along one side of the horizontals and upper halves of the uprights most useful to prevent pulleys moving out of place. These screw nails project one inch from the wood. The equipment for extension, ropes, single and double metal pulleys and sand bags, are provided at a reasonable figure from the bazar. A good tin of Sinclair's glue, which can adhere apparently whatever the weather, with a set of transfixion instruments to meet the unusual case in which loss of skin or expensive wounds preclude the use of Sinclair's glue, assist one to treat the majority of fractures with equanimity and interest. I would here remind you of the excellent and recently described method of using the elevation system of the modern operation table to obtain extension of fractures of both bones of the leg before applying plaster. I have found so far, that a loop of fine *nawar* stitched round the ankle renders a transfixion pin unnecessary.

All is now easy. A visit to the wards too often brings us to the bedside of one of those sad young patients, a child with a tuberculous hip, with anxious parents near-by. A message is sent to the *mistri* to bring his model of a double Thomas' splint. This model is laid alongside the child—the measurements from the heels, with abduction required, are recorded with chalk on the flat wire model in the *mistri's* presence and the appropriate prescription for Messrs. Dutta Brothers is written and handed to the parents, telling them the cost; in this case Re. 0-11-6. They procure the flat iron rod and rivets, hand them to the *mistri* in the hospital and assist him usually in the building of the frame, which is less than two hours' work. The *mistri* hands the frame to the nurses, who quickly wrap on a padding of old strips of condemned blankets and sheets, the parents then take the frame to Dean Brothers with the information that the splint will be completed for Rs. 3 and with any luck that child should have its splint on next morning; cost Rs. 3-11-6. The strict accountant might add two pice more for coke and condemned sheeting. For the application of the splint—the *mistri* is present with his bending pliers but he usually has the curves on the stems and cross pieces so accurately that one's hands alone can do the rest to make these lighter frames fit comfortably.

The most expensive splint we make is the double Thomas' hip splint for adults—this costs Rs. 5 or by stricter audit, Rs. 5-0-8. I have one patient in Ranchi who has worn one of these for the last two years. He had both pulmonary and hip disease with sinuses. I originally applied two plasters in which he contrived to exist for six months; a stout patient in both senses of the word. His sinuses healed in the frame and he has been afebrile and sputum-free for about 18 months. He recently developed renal colic, which indicates the necessity of turning such patients on their faces, at regular intervals, for renal pelvis drainage. It is also advisable to turn their beds round occasionally to prevent faulty attitude and pain in the neck—as they tend to look constantly towards the most acceptable view. This is particularly necessary with children. The proximity of Itki Sanatorium to Ranchi provides extra scope for this work when patients in charge of Dr. Muthu require immobilization for tuberculous bone disease.

All the hospitals and dispensaries in this district have been provided with two sizes in Thomas' knee splints with a view to the better treatment of fractures of the lower limbs and acute knee joint conditions and the safer transport of such injuries as the modern motor car provides in outlying areas. The cost of each splint was Re. 1-8-0.

It would be too much perhaps to expect that the local manufacture of splints or such equipment for your hospital will appeal to all, but I would emphasize its simplicity when the preliminary arrangements are complete. If taken up, even in the most modest way, as we are doing here, I am sure you will find it a blessing to all—the patients, the nurses, the dressers and yourselves. Should any one consider his hospital or dispensary too small to work on iron splints, well, he can always work in wood and wire. For this purpose a tool box containing a saw, a chisel, a hammer, wire-cutting pliers, a tape measure, wood awl, screw driver and screws and nails, with pieces of wire, round and flat, *nawar* tapes of sizes and a tin of Sinclair's glue will make it possible for you to deal with the occasional fracture or joint infection with some degree of confidence and comfort. It has been my experience, as a rule, that if equipment is available it will be used—if not available, a *laissez-faire* attitude is liable to be adopted.

There is nothing undignified in getting down to such a job of work as making or seeing your own splints made, and in doing so we are only trying to follow the greatest names in the profession of surgery, and I would ask you to deliberate on the remarks of Hey Groves', one of the greatest artificers of the day, 'that the proper treatment of fractures is not only a scientific problem or a philanthropic duty, but also a business proposition. In other words it pays to treat fractures well' and I leave you to

(Continued at foot of next page)

THE TREATMENT OF OTITIS MEDIA*

By B. N. C. ROY

Late Visiting Surgeon, Carmichael Medical College Hospital, Calcutta

A busy general practitioner is much more frequently faced with the difficulty of handling a case of acute middle-ear disease than is the ear specialist. In the beginning it is so painful and distressing, particularly if the subject be a child, that it demands urgent and careful attention. Whatever is done it must assure immediate relief and produce restful sleep.

The acute symptoms take about ten days, and the discharge about twenty to disappear. The hearing comes back to normal in about a month's time. This kind of termination, without complications, is highly satisfactory. There are, however, occasions when one's best attempts and vigilant care are of little avail. Here, the type is virulent; the temperature is steadily rising; the pain is growing worse, the tympanum is red and bulging or has given way early and the discharge is profuse; the mastoid region is œdematous and tender, or meningitic symptoms are slowly appearing. The type may not be virulent or fulminating, but either the temperature is persistently high, the pain is steadily increasing, or mastoiditis, meningitis, or some other complication is unexpectedly appearing and interfering with the general progress of the case. Now, the responsibility of the family doctor is great. He is in need of assistance and better counsel. It is for him to advise the patient what to do—to seek the help of an aural surgeon, or that of an electrotherapist. I would not make this distinction except for the reason that very few of the ear specialists, so far as I know, are in favour of regular electrotherapeutic measures. There is little reliable information on this subject in the literature.

In my opinion electrotherapy can be solely relied upon for the immediate relief of symptoms such as agonizing pain, sleeplessness, vertigo, high temperature, etc., for checking the progress of the disease, and for preventing complications. This treatment can be resorted to at any stage of the disease, and the results are uniformly satisfactory.

Acute otitis media, when idiopathic, may have merely an exposure to cold or other insignificant thing acting as an exciting cause. General malaise, or fretfulness in a child, ushers in the

disease. In a good percentage of cases it is a complication secondary to an attack of influenza, tonsillitis, pharyngitis, adenitis, alveolitis, pneumonia, typhoid, measles, scarlet fever, mumps, etc. The causative organisms may be streptococci, influenza bacilli, pneumococci or meningococci. Innumerable others may be present when the communication is established with the external ear.

The temperature gradually rises. The patient complains of severe pain, usually in one ear, of an agonizing character, and either persistent or intermittent. The pain may be so severe as to radiate all over the face, head and neck of the affected side. It is the maxim of the experts in diseases of children that, when a child suddenly wakes up with a shriek, in the majority of cases, it is for earache. The pain gradually grows worse. The aching ear is usually kept away from the pillow. Auriscopy helps very little at this stage. In a good number of cases, at this stage, the analgesic and the antipyretic powders, along with the instillation of soothing ear-drops, are all that are necessary.

But when there is no response to these ordinary measures, one or two ultra-short-wave exposures, at this early stage, will not only check the progress of the disease but also give the patient immediate relief as regards pain, and in twenty-four or thirty-six hours' time the *status quo* is likely to be established.

Electrotherapy may be of immense value at later stages. It is helpful when the temperature is high and persisting; when one is in doubt whether it is still in the catarrhal stage or has suppurated; when there is a bulging of the drum, or the drum is perforated and the discharge is increasing, or has stopped suddenly with great aggravation of pain; when there is œdema and pain over the mastoid region; when one school of surgeons insists on an 'early paracentesis' of the bulging drum and the other school, more conservative, will rely on instillations and insufflations; when we do not hesitate to blame the transitory granulation tissue as it fills the aural cavity—Nature's triumphant effort to entangle and check the infection, and which slowly gets absorbed as the infection subsides making room for the ossicles to have their full play and perform their work as usual; or when these granulations are considered to be exuberant, interfering with the proper drainage and preventing the union of the drum. It is in these cases that electrotherapy should be given the trial first.

Volumes are written on the different methods of mastoidotomy, their suitability, indications, contra-indications, complications, after-treatment, causes of failures, mortality, and so forth. But all these, in the light of modern methods of electrotherapy, are purely of academic interest.

I have not seen as yet one case of acute otitis media to usher in mastoiditis, or any other complication where electrotherapy was tried early, nor I have lately seen a case complicated with

* A paper read at the clinical meeting of the British Medical Association, Calcutta, on 12th August, 1938.

(Continued from previous page)

reflect on what is to be done, especially for these young patients in India with tuberculous disease of the spine and hip, unless we can provide them with some form of frame-splint immobilization. Certainly plaster of Paris or the purchase of ready-made splints is not the answer for the immediate future.

mastoiditis, meningitis or cervical cellulitis in various stages which did not respond to ultra-short-wave exposures, when the intensity and wave-length are correctly chosen.

From the point of view of electrotherapeutic treatment it is much more convenient to divide all cases of otitis media into the following main groups:—

I. Stage of acute onset

This stage is usually over by the tenth day. It may end earlier, under treatment, if the infective organisms are exceedingly virulent. Pain and fever are the prominent symptoms. Bulging and redness of the drum appear later. Ultra-violet, diathermy, or ultra-short-wave exposures will give immediate relief to pain, and the course of the disease will be reduced to twenty-four or forty-eight hours.

II. Stage of active discharge

This stage, in the normal course, is usually over by the twentieth day. The drum is perforated in due course, or artificially. The discharge, high temperature and pain may persist. Deafness, tinnitus, vertigo and the throbbing sensation are usually there. The mastoid region may be tender. Polypoid granulations may have made their appearance.

Diathermy combined with ultra-violet, or ultra-short-wave alone will stop the pain and the discharge. The temperature will drop. The mastoid complications will quickly subside. The length of treatment required is usually from four to seven days.

III. Chronic stage

Here the pain is moderate. The discharge may be profuse, very slight or absent. The mastoid region is either painful and oedematous, or if mastoidotomy is performed it has no effect on discharge, hearing, etc. The cervical glands are enlarged and inflamed. There may also be difficulty in opening the mouth and in proper mastication. There may be daily or occasional rigor and fever. There is distinct loss of hearing on the affected side.

The average time taken for electrotherapeutic treatment, at this stage, is from seven to ten days. The type of treatment will vary according to the salient features of the case. In certain cases of chronic discharge ionization gives wonderful results.

IV. The fourth group may be called the sequelæ

There may be recurrent attacks of otitis, mastoiditis, or cervical adenitis. Persistent deafness, giddiness, tinnitus, anæsthesia or hyperæsthesia of the temporal, facial, occipital or cervical region are frequently met with.

The methods of treatment are so varied that it is difficult to enter into detail in a small compass like this. Fever-therapy has a great scope in dealing with these sequelæ.

No doubt there are benign and virulent forms. But nothing besides electrotherapy can bring

about such prompt relief of the distressing symptoms and curtail the course of the disease to such a minimum, whatever the type, nature or virulence of the infective organisms may be.

The results of electrotherapy are fairly uniform. Age, type of bacteria, associated exanthems, or general health seldom vitiate the results.

Complications like meningitis, mastoiditis, facial paralysis, cellulitis of the neck, etc., rarely occur; mortality should be unknown; the discharge stops fairly quickly; the normal hearing is soon re-established; the risk, trouble, time of an operation, or slow conservative treatment can be avoided; if early and efficient electrotherapy is resorted to.

It may not be out of place if I quote here the observation of one of the present authorities on the subject. The time of healing after mastoid operations varied from eleven to one hundred and fifty days (Campbell, 1936). Compared with this the maximum of about a fortnight's treatment for the very worst case, even for those who have undergone repeated mastoid operations without much relief of discharge, pain, or loss of hearing, should be of more than ordinary interest.

There was a time when I was keen on making repeated trials to get the best pictures of the mastoid region. Much energy and time I spent on determining the positions, measurements, angles, densities and a hundred other details to find out exactly whether the condition was cellular, diploic or sclerotic. I had long discussions with experts to find the best way to read those pictures. But now I am fully convinced that it is simply immaterial what the reaction in the mastoid cells is like. The fundamental point is the infection and that must subside. The assistance of a treatment is required to master the situation—to stop the infection. When that assistance is given, Nature will do her demobilization part successfully.

Time and labour were equally expended, year after year, on the bacteriological investigations of the causative organisms, on their variety and classification, on morphological and cultural characteristics, on virulence, pathogenicity and other biological activities, and on their toxins and enzymes. I am convinced now that the modern weapons that have found their place in an electrotherapist's laboratory will make no distinction of the class, form, number or virulence of the infective agents. It matters not whether they are exposed on the surface or hidden deep under the periosteum or in the medulla of a bone or in the base of the skull. The undepressed penetrability of these rays, the absolute certainty of their germicidal power and the toning effect of these rays on the healthy tissues, which brings back the *status quo* in any situation, are the facts that can be confidently relied upon.

PRIMARY AND SECONDARY TUBERCULOSIS

By P. G. GOLLERKERI, M.D.

*Department of Pathology and Bacteriology, Medical
College, Rangoon*

THE common infection of tuberculosis in the adult is usually a comparatively chronic lung

(Continued from previous page)

Electrotherapy is the only method, we have at our disposal, which can kill the infective organisms, and can stimulate and invigorate the polynuclears and round cells, without causing any damage or interfering with the normal functions of a single healthy cell which is performing its protective or nutritive function for the welfare of the host.

There is, of course, another side of the question. Everything has its own place, and no method of treatment can be considered as ideal, where one hundred per cent success can be guaranteed. It is just as much a mistake to suggest an elaborate and expensive electrotherapy for every case of middle-ear disease, before the ordinary, standard methods of treatment are tried, as to hurry the patient on to the operation table before electrotherapy is given a fair trial. I suggest this because electrotherapy is the simplest, cleanest and the least injurious method of treatment by which surgical or any other troublesome intervention can be spared in the majority of cases.

Judging from the frequency and importance of partial or substantial incapacity as it results from the complications of otitis media, I believe that the general standard of training in this particular branch of surgery should be raised. The simpler methods of treatment, methods that are efficient to cure a case running a normal course in reasonable time, and that are competent to prevent complications should be thoroughly impressed upon the minds of the young medical men, so that the general practitioners will be able to manage most cases and few will require any further assistance and special treatment.

If the occasion for any expert treatment does ever arise, electrotherapy should be given a trial first. In the majority of cases it will not fail. If it does, the question of surgical or any other intervention will necessarily arise, the surgeon should be particularly careful in tackling these cases. Electrotherapy seldom fails if there is sufficient tissue resistance left to make use of the rays and currents; the services of the physician, surgeon or electrotherapist are of no avail when that is lost. The surgeon deserves extra credit if he can help the patient when the situation stands thus.

REFERENCE

Campbell, A. (1936). *Brit. Med. Journ.*, Vol. I, p. 788.

condition with the oldest lesion located somewhere in the apex of one of the lungs, more commonly the right. This apical lesion in the early stages is not easily recognizable clinically, giving only a few crepitations from a confluent tuberculous focus. Later on, this confluent caseous mass becomes liquefied and is partly absorbed and partly expectorated in the sputum, leaving a cavity behind. It is easier to diagnose the condition in this stage than in the first stage already referred to. These lesions, because of their chronicity and their slow progress, are considered in the light of modern experimental work on animals as lesions of secondary tuberculosis. It is presumed that the primary lesion, the Ghon lesion, has already occurred in these cases with complete recovery and the development of a degree of immunity which subsequently broke down to give rise to the secondary infection and chronic lesions.

Thus, tuberculosis occurring among adult city-dwellers tends to be of the secondary chronic type, as they have more frequent chances of primary infection of a low virulence, which, short of producing clinical symptoms of disease, gives rise to an immunity phenomenon that breaks down only when the second infection happens to be of a sufficiently large dose of marked virulence, or when the vitality of the subject is greatly lowered. In urban children there is always the menace of a primary infection, which, if they have normal health, may affect them beneficially, producing a degree of protective immunity against clinical tuberculosis; this is probably what happens to the majority of modern city-dwellers. On the other hand, if the child's general health is indifferent from any of the various causes of malnutrition, etc., the child may fall a prey to the infection and die of it in a short time. The lesions in such a case are usually the typical Ghon tuberculosis—an exudative caseous necrosis affecting large areas of the lung parenchyma and with less tendency to cavity formation than in the secondary type.

There is another aspect to the question of immunity in tuberculosis. The milk-borne infection common enough in cities is a bovine bacillus infection giving rise to enlargement of mesenteric and other lymph nodes which may clinically be large enough for removal by operation, and it is not fatal like the lung infection. Also, development of a bovine tuberculosis in lymph nodes, etc., in humans appears to immunize the individual to infection with the human type of bacillus—a more deadly infection—as it prefers a vital organ like the lung for its activity. It is therefore unusual to find lesions typical of the two types in one and the same individual.

The case about to be described gives food for reflection as to the possibility of a bovine bacillus changing its virulence and assuming the characters of the human bacillus, or a bovine infection not producing sufficient

immunity to protect the individual from a subsequent human infection.

Case.—Chinese female, *et.* 1 year 5 months, was admitted into the Rangoon General Hospital on 11th September, 1938, for treatment of cough and fever of 30 days' duration which had become worse four days prior to admission. On examination the lungs were 'full of râles' from the front. Consolidation in the upper part of the left lung gave the clinical diagnosis of broncho-pneumonia, left lung, with marasmus. Slight oedema of both legs was noticed. The infant was 'gasping for breath' when admitted and within two hours of admission died.

Post-mortem examination.—An extremely emaciated female child of about 1½ years with a normal skeletal growth, but a notable anaemia and much wrinkling of skin giving the 'old age' look said to be peculiar to congenital syphilis. On opening the chest a little clear fluid was found in the pleural cavities but no adhesions were apparent. The left lung in the greater part of its upper lobe showed a consolidation very like a pneumonic consolidation. The rest of the lung was fairly crepitant. The other lung was normal to the feel. When the abdominal cavity was exposed, the true nature of the condition became evident. The mesenteric lymph nodes were enlarged and matted together into a large mass with ramifications into the porta hepatis, the lesser curvature of the stomach, the pelvic and other fossae; in fact there was no part of the abdominal cavity that did not show a tuberculous caseous mass. In the region of the caecum and the last six inches of ileum, the process seemed to have infiltrated into the lumen of the gut and to have given rise to ulcerative lesions in it. The peritoneum as a whole did not appear to be involved in either a miliary or metastatic spread, except in the ileo-caecal region where groups of small tubercles were present on the serous areas corresponding to the ulcers noted above. The lungs were next taken out and examined in greater detail. The left lung was cut open longitudinally from apex to base to display the consolidated upper lobe. Its naked-eye appearance confirmed with the textbook description of pneumonia caseosa. There was no cavity formation. The staphyloid grouping of tubercle follicles typical of the common secondary lesions in the adult were altogether absent in both the lungs. The right lung, but for a small degree of oedema, did not show any pneumonic or tuberculous lesion. A mild fibrinous pleurisy was present over the consolidated part of the left lobe. The pleura elsewhere was free and transparent. The pericardial cavity contained half a teaspoonful of clear fluid with no adhesions between the surfaces. The mediastinum displayed another mass of caseous glands. A careful search was made over the surface of the brain. This was rewarded by the finding of two small greyish-yellow obviously caseous masses in the pia-arachnoid along the Sylvian fissure on one side. Smears from one of these, from the lesions in the left lung and the mesenteric nodes, all showed acid-fast bacilli in large numbers.

Histological sections were made from the lesion in the lung and the lymph nodes and examination confirmed the diagnosis of caseous pneumonia and tuberculous caseation of lymph nodes, respectively.

The spleen, liver, kidneys, adrenals, etc., did not show macroscopic tuberculous lesions. The Wassermann reaction (post mortem) of the serum was negative. With these findings a diagnosis of *tubercles mesenterica*, pneumonia caseosa, ileo-caecal tuberculosis with early involvement of the meninges was made.

In the discussion that followed the post-mortem examination the following points were brought out for explanation:

(1) Clinical human tuberculosis, whether with the bovine or the human bacillus, occurs as a bacteraemia; modern cultural methods have proved this almost beyond a doubt. In the present case occurrence of widespread lesions including those in the meninges confirms this probability.

(2) Bovine tubercle bacillus has a greater predilection for the lymphoid tissue of the body, as shown by the older lesions in the mesenteric lymph nodes in the present instance. Primary mesenteric and intestinal tuberculosis in children has been shown to be a milk-borne infection with the bovine bacillus.

(3) If it is conceded that primary infection with the bovine bacillus confers an immunity against the human bacillus infection then the lesion in the lung which is certainly the more recent in this case is also due to the original bovine infection. It is well known that primary infection with the human bacillus gives rise to lesions in the lung *par excellence* like the one seen in this case, to the exclusion of affection of lymphoid tissue. Is it possible that the original bovine bacillus has in the course of its infection and proliferation in the human body so increased in its virulence as to simulate the human bacillus and to give rise to the lesion in the lung? The other way of looking at it is that a bovine bacillæmia results in such a devitalization of the soil as to produce any kind of lesion in it. It is not uncommon to find at post mortems on pulmonary tuberculosis subjects that fibro-caseous lesions with cavities often coexist with patches of pneumonia caseosa, or miliary or metastatic tuberculosis in the lungs and other organs in the body.

(4) What are the laboratory aids that could be marshalled in a case like this to make an ante-mortem diagnosis of tuberculous pneumonia? The difficulty of collecting sputum from infants for the demonstration of the bacillus is notorious. Swabbing the throat is at best a hit-or-miss affair. The culture techniques for tubercle bacillus are impracticable for routine laboratory use and quick diagnosis. X-ray examination of the lungs no doubt will reveal the pneumonic condition, but the difficulty will be that of spotting it as a tuberculous condition.

ATYPICAL AMYLOID DISEASE OF THE LIVER

By M. D. ANANTHACHARI, M.B., B.S.
(General Hospital, Madras)

WITH the disappearance of instances of long-continued suppuration and chronic destructive disease, cases showing amyloid degeneration have become exceedingly rare. Only one case is recorded among the autopsies at the General Hospital, Madras, during the past twenty-five years. When cases are detected on the autopsy table, unsuspected during life, it becomes evident

(Continued from previous page)

A total leucocyte count theoretically should give a negative finding as compared to the usual positive finding in a coccal pneumonia. A relatively large percentage of lymphocytes in a leucopenic total count is also found in other conditions like congenital syphilis and marasmus from any cause. Of course, a positive leucocytosis with a good percentage of neutrophile polymorphonuclears may be used as a guide in diagnosing such a case as a coccal pneumonia. An immunological reaction such as von Pirquet's is useful probably only when it is negative. Thus we are confronted here with a highly unsatisfactory state of affairs in diagnosing a not uncommon condition.

It is notable that none of the external groups of lymph nodes showed any enlargement or clinical evidence of tuberculosis, as if they did, a biopsy could have given a clue to the condition.

Unfortunately, no cultures were made from the post-mortem material to identify the type or types of organisms at work in the different sites, as the special media were not available at the time.

Summary

A post-mortem examination on an infant dying of pneumonia caseosa and tuberculous involvement of lymphoid tissue in other parts of the body is described. The problem of immunity in tubercle bacillus infections and laboratory aids in the diagnosis of these conditions is discussed.

[Note.—We have no doubt that phthisiologists will have ready answers to the questions the writer has raised.

It is unfortunate that he was not able to identify the type of the organisms found in the intestinal glands and lung lesions. Whilst the bovine type usually gives rise to gland or bone lesions, it does occasionally produce lung lesions.

We cannot agree that a von Pirquet reaction would be of use, even if it were negative in such a case. It could be interpreted as indicating the absence of tuberculous infection or the absence of any resistance to tuberculous infection.—
EDITOR, I. M. G.]

that association with chronic suppuration and tissue destruction are not the invariable antecedents of amyloid degeneration. It is stated that amyloid disease may be found in association with malaria after long-continued infection or repeated attacks (Gibson, 1936; Boyd, 1938). Such post-mortem revelation has resulted in the necessity to suspect amyloid disease, even though no apparent basis for this diagnosis is noted (Bannick *et al.*, 1933). It is possible that the condition escapes recognition because it is not suspected.

Bennhold (1923), working with the dye Congo red as a stain for amyloid tissue, pointed out that intravenous injection of this dye would disclose the presence of amyloid disease during life. As a result of this report Congo red has been extensively used in suspected cases of amyloid disease and ante-mortem diagnosis has become possible. Tests both quantitative and qualitative are described and their value as clinical aids to diagnosis appraised. Through this test it has also been made possible to recognize that the process of amyloid degeneration is reversible and that improvement is possible in cases where the cause can be removed (Wallace, 1932; Walker, 1928).

Waldenström practised a system of bio-puncture suggested by Arnold Josefsen. He diagnosed the disease by examining the material withdrawn by puncturing the liver with a hypodermic needle. Of interest is his experience that, even in a patient undoubtedly suffering from amyloid disease, the hepatic cells aspirated by a fine needle are always healthy, unless a piece as large as a liver acinus (about 1.5 mm. diameter and 2 cm. in length) is removed. He concludes that a probability from more clinical evidence becomes a certainty by such examination.

Depending as it does on the mass of existing amyloid tissue in the body, the Congo-red test has its limitations. It is not possible that the test will reveal early cases. Bennhold observed that patients with extensive amyloidosis, especially, amyloidosis of the liver, practically all gave positive Congo-red tests and that it was only when the deposits of amyloid were not extensive that one might obtain a negative Congo-red test. In the case under report this statement is probably borne out.

Is it possible that amyloid disease could arise primarily without any discoverable cause? Perla and Gross (1935) raise a point whether some previous suppurative process might not initiate a disturbance in protein metabolism, which would survive the initial perverse impetus. Boyd (1938) mentions a case where there was extensive amyloidosis without any discoverable cause at autopsy. Only very few cases appear to be reported where there was no cause. Might it be that in such cases diet produces a disturbance which hitherto was conceived to be initiated only by tissue destruction? Experimental evidence suggests that diet, particularly cheese,

has its share of influence in the aetiology of the disease. It is also not known what it is that determines the site of such changes or how it is that in certain cases the amyloid change is diffused and in certain others it is localized as tumour mass.

Case record.—A man, aged 35 years, was admitted into the wards of the General Hospital, Madras, for pain and enlargement of the abdomen.

A labourer, he was a poorly nourished man with a protuberant abdomen which he complained was gradually becoming harder and bigger. He had pain round the waist and in the epigastric region, particularly after food though his appetite was good. He was not constipated. There was nothing abnormal in his diet.

On palpation of the abdomen the liver was felt as a hard mass extending across the epigastrium to the left hypochondrium. It was firm, smooth and painless and had a rounded edge. In the left hypochondrium it felt slightly harder in consistency than elsewhere, where it simulated very closely in all clinical details an enlarged spleen. For diagnostic purpose the mass in the left hypochondrium was punctured with a hypodermic needle of fairly large bore. The aspirated material was a clear jelly-like substance of the consistency of boiled sago, without any trace of blood in it. The material was sent to the pathologist and his report is appended.

Screening the stomach with barium showed that it was normal in shape and movements. It appeared pushed forward and to the right.

There was neither anaemia nor jaundice. His urine was normal. The van den Bergh test was negative and the icterus index 7 units. Blood cholesterol was 179.4 mgm. per cent. The aldehyde and Chopra tests for kala-azar were negative. Blood serum for Kahn's test was negative.

To eliminate the possibility of a latent focus of sepsis, white blood cell counts were repeatedly done and the maximum count was only 9,900 cells per c.mm. Armet's count showed no shift to the left. Sedimentation rate, according to Zeehwer and Goodall, was 2.4 cm. in 1 hour. Functional test for liver with leuculose was normal.

To verify the histological findings Congo-red tests were carried out according to methods described by Taran (1937) and Todd and Sanford (1935). Both the tests gave normal healthy figures.

The patient according to his statement felt better and at the end of two months gained eight pounds in weight. He left hospital at his own request and against advice, with the liver in the same condition.

Pathologist's report.—Smears stained with methyl violet show small masses of metachromatically (pink) staining, wavy, branching macaroni-like bands of a homogeneous substance, with fine bluish-staining fibrils separating the individual strands. Occasionally, scattered between these masses of pink-staining cylinders are clusters of large polyhedral cells (staining blue) which in some places appear compressed and elongated. A few collections of degenerate leucocytes are also seen. The endothelial lining of the capillaries which can be clearly distinguished in some places appears to be free from Leishman-Donovan bodies.

The general appearance is not unlike that of a smear of an amyloid liver in which extensive amyloid deposition has led to marked disappearance of the parenchyma cells.

Comment

The outstanding points in this case are the absence of any clinically discoverable cause for the condition; the difference between the two parts of the enlarged liver, the failure of the Congo-red tests, and the normal function of the liver. Autopsy elucidation was however absent

That none of the known causes for amyloid disease is present cannot be asserted in this case. There is however no evidence of chronic sepsis or suppuration. Might it be that the causes for the enlargement for the right and left halves of the liver are different, the left lobe alone being affected by amyloid disease? Rosenblum and Kirshbaum (1936) in classifying amyloidosis mention a possible localized involvement with amyloid, which may occur within neoplasms or chronic inflammatory areas. Such would explain the failure of the Congo-red tests on the basis of insufficiency of amyloid material to give a positive test. The absence of ascites, jaundice, the good functional condition of the liver, in spite of its size, are points of interest.

In this connection, it is to be noted that Paunz test is associated with certain practical difficulties. The amount of Congo red to be injected is bulky. It is sometimes found difficult to draw blood at the end of one hour, as the rapid coagulation of the blood in the needle interferes with aspiration. A similar observation is made by Wallace (1932) and Becker. The test is not delicate and it is useless in early cases. Its only virtue is that it can be carried out in places where colorimetry is not possible.

Wallace (1932) claims that the Congo-red method possesses obvious advantages over Waldenström's bio-puncture. According to him it gives a quantitative result and is somewhat less drastic. In the case reported, without the puncture the disease would certainly have been missed. Where suspicion of the disease is strong from clinical evidence and requires only confirmation the Congo-red method will be the choice. In other cases where the clinical history does not lead to suspicion at all or where the disease is very early, bio-puncture alone can supply unequivocal evidence. The method of bio-puncture is not however available where kidney alone is the site of amyloid disease and where the liver and spleen are not enlarged for safe puncture. Where the kidney is affected early, the disease is more readily recognized by examination of the urine and the associated clinical evidence of poor kidney function. It is in cases in which the liver or the spleen alone is involved primarily that, if a Congo-red test, which is not infallible, fails, the disease will be altogether missed.

Summary

1. A case of amyloid disease of the liver with unusual features is reported.
2. The usefulness of the Congo-red test and bio-puncture is discussed.

Acknowledgment

I am grateful to the superintendent, General Hospital, Madras, for permission to publish this case.

AN INVESTIGATION OF CALCUTTA MILK SUPPLY FOR PRESENCE OF TUBERCLE BACILLI

By R. K. GOYAL, F.R.S.E., D.Sc., M.R.C.P.

and

S. LAL, M.B., B.S.

From the Bacteriological Department, School of Tropical Medicine, Calcutta

IN view of the growing interest and increased incidence of tuberculosis in India, it is extremely important to determine the various sources of dissemination of tubercle bacilli. It has been estimated that as many as 40 per cent of cattle are tuberculous in certain parts of England and about 7 per cent of samples of milk in London contain tubercle bacilli. Although milk is generally boiled in India before consumption yet the intimate contact of cattle and people in India calls for a searching enquiry into the incidence of tuberculosis in cattle in this country. We have approached this problem by examining the milk supply of Calcutta for the presence of tubercle bacilli.

The presence of tubercle bacilli in milk has been determined in Europe by centrifuging a certain amount of milk, pooling the cream and the deposit and injecting it into two guinea-pigs. We found that this method could not be adopted in Calcutta. The injection of the mixture of cream and the deposit led to the death of the guinea-pigs within 48 hours. In the next experiment, milk was received directly from the udder into sterile test-tubes, but the guinea-pigs inoculated with the pooled samples died in 4 to 20 days. An examination of 14 samples of milk revealed the presence of the following organisms:—(1) streptococci, (2) pseudo-anthrax bacilli, (3) yeast-cells, (4) *B. tetragenus*, and (5) lactose fermenting Gram-negative bacilli. The microscopic examination of the smears of the mixture

of the cream and the deposit from centrifugalized milk failed to show the presence of acid-fast bacilli. We then adopted the following method which proved fairly satisfactory:—

Sixty c.cm. of milk were centrifuged for 30 minutes at 2,500 r.p.m., the cream and deposit were pooled and treated with four times their volume of 5 per cent NaOH for 30 to 45 minutes, and the mixture was shaken thoroughly every five minutes. It was then centrifuged for 30 minutes at 2,500 r.p.m., and the deposit was neutralized and suspended in sterile normal saline. Two guinea-pigs were injected intramuscularly with 5 to 10 c.cm. amounts. In spite of these precautions, it was found that an injection of 10 c.cm. often caused the death of the animals within 18 days, hence the amount was later reduced to 5 c.cm. The inoculated animals were tested at intervals of a fortnight by an intradermal injection of 0.1 c.cm. of a 1/10 dilution of tuberculin. The animals not reacting to tuberculin were kept under observation for at least three months and then sacrificed. The post-mortem examination was done very carefully and films of the suspected organs were examined for presence of acid-fast bacilli.

The samples were collected from various areas of Calcutta, both from the dairies and individual milkmen. One hundred and eleven samples were examined, each sample represented milk from 5 to 15 cows. As 31 samples caused the death of the guinea-pigs within 18 days, only 80 samples were left for consideration. Seventy-eight out of the 80 samples gave completely negative results, the tuberculin reaction was faintly positive in two cases, the animals were found to have a small abscess at the site of inoculation and the corresponding glands were slightly enlarged. Filamentous acid-fast organisms characteristic of actinomyces were found in films. A suspension of the suspected organs was injected into a series of two new guinea-pigs and a rabbit; it was found to be non-pathogenic.

Discussion

An examination of 80 samples of milk from various areas in Calcutta failed to reveal the presence of tubercle bacilli. As each sample was derived from at least five cows, it is clear that at least 400 cows were examined. The absence of tubercle bacilli in milk does not necessarily mean the freedom of cows from tuberculosis. Taylor (1918) examined 6,490 slaughtered cattle at Ferozepore, 3.4 per cent had tuberculous lesions, practically all of them were of a localized nature. The microscopic examination revealed the presence of acid-fast bacilli in 60 out of 2,701 cattle (2.2 per cent). Soparkar and Dhillon (1931) examined 1,116 slaughtered cattle at Lahore, 255 or 22.85 per cent were found to be infected with tuberculosis and tubercle bacilli were detected in the smears, some more animals were found infected by the animal tests. The rate of infection varied with different kinds of animals examined. In cows it was 21.3 per cent, in buffaloes it was 23.6 per cent and in bullocks it was 31.6 per cent.

PROTECTION OF ANTI-PLAGUE WORKERS

By R. C. BHARGAVA, D.P.H.,
District Medical Officer of Health, Ballia

With the advent of gassing of rat holes and other efficient methods of disinfection and disinfection, it seems necessary that greater attention should be paid to the protection of anti-plague workers.

All the workers down to the coolies and peons should have a thorough knowledge of the ways in which plague spreads through fleas, the habits of fleas and also of the ways in which pneumonic plague spreads.

All the workers should have proper uniforms. I should suggest white uniforms; the uniforms should be white from the top to bottom, i.e., white boots, white putties, white trousers, white coat and white neck and face protector. If no putties are worn, the trousers should be longer than usual. The boots should be without laces and holes. Such boots can be made by incorporating elastic into the sides. The coat should have a high and tight collar. The head and neck protector should consist of a bag of cloth which will cover the whole head and neck with a high and well-fitting collar at the lower end and a purse string at the top of the head. There should be holes for the eyes. Materials for a mask and goggles should always be ready in the pocket.

Protection of hands is necessary for those who are engaged in the cyano-gassing. It is possible that fleas may attack the hands. Fleas are now and then found on the hose pipe and these will attack the hands if the coolie is unwary.

(Continued from previous page)

With regard to the presence of tubercle bacilli in milk Joshi (Datta, 1935) and Gloster (Datta, 1935) examined at least 775 samples, but could not demonstrate any tubercle bacilli by guinea-pig inoculation. Joshi (Datta, 1935) found acid-fast bacilli in 47 out of 674 samples (7.6 per cent), but these were non-tuberculous to guinea-pigs. It is possible that some of the acid-fast bacilli seen in the smears from the organs of cattle were not mammalian tubercle bacilli. Further work is required to elucidate this point.

Summary.—An examination of 80 samples of milk from various sources in Calcutta failed to reveal the presence of tubercle bacilli.

For the protection of hands during cyano-gassing operations in the infected locality, I should suggest a glove of thick rubber protecting the coolie from the tip of the fingers to the elbow.

This uniform has been suggested for the following reasons, which anti-plague workers should always keep in their minds :—

Fleas are often found in the streets of infected villages because people throw the dead rats out.

Infected fleas are almost invariably found in the infected houses and will jump up on the legs of anyone entering.

Infected fleas may fall down from the rats in the roofs of the infected huts when the roof is of thatch or tile.

Pneumonic complications may be present in cases of bubonic plague and one must always have masks and goggles ready.

Anti-plague workers should cultivate the habit of stamping their feet on the ground so that fleas may be shaken off if any be there.

Plague workers should always work in batches of two, so that they can scrutinize each other's uniforms, as it is certain that fleas will be found on persons entering plague-infected houses, of course most frequently on the boots and the putties. If any fleas are seen they should immediately be killed with kerosene oil, which should always be ready at hand.

Plague workers should not be given too much work or else they are liable to become careless. They have to keep standing throughout the period they are in the infected area and they have to keep on their guard continuously. Under such conditions the periods of rest are essential.

When entering an infected house, disinfection should be begun from the very door. All the dead rats and dead bodies should be thoroughly drenched with kerosene oil emulsion of sufficient strength. No place should be entered until thoroughly drenched with kerosene oil emulsion.

All the staff engaged in anti-plague work should be vaccinated against plague without fail beforehand.

Plague is a winter disease and clothes are often so coloured as to conceal the flea. Fleas found in the plague-infected houses are almost black and will be easily concealed on a woollen cloth of dark blue, brown and red colours. Plague workers should avoid these colours. I have suggested white above for the sake of contrast. White boots and putties suggested above should be kept as white as possible.

It may be objected that in winter woollen clothing is necessary. Woollen underwear can be used and that should suffice if work is carried on during the warmer period of the day, and this

A NOTE UPON AN INTERESTING SEROLOGICAL TYPE OF LEPTOSPIRA IN THE ANDAMANS

By B. M. DAS GUPTA

Calcutta School of Tropical Medicine

IN course of their investigation into leptospirosis in the Andamans, Taylor and Goyle (1931) isolated the causal organisms from 28 cases and differentiated them into two distinct serological types, namely, Andamans CH11 and CH31. They further showed that the type strain CH11 was unique in that it was serologically distinct from several strains of leptospiræ isolated in different parts of the world. Lately, by the courtesy of Major B. Chaudhuri, I.M.S., Senior Medical Officer, Andaman and Nicobar Islands, some sera of the cases of Weil's disease were received. One of these failed to agglutinate the type strain CH31 and gave only a little reaction with CH11. As the clinical manifestations exhibited by the patient were very suggestive of Weil's disease, we tested the serum against three other strains in our possession, but none showed even a slight evidence of agglutination. The remainder of the serum was, therefore, sent to Professor Schüffner at Amsterdam for testing against several other strains. (He keeps a large stock of leptospiræ of different

(Continued at foot of next column)

(Continued from previous page)

period is best suited for work among the poor people as they seldom have warm clothes.

[Note.—We submitted this for an opinion to an experienced officer. His comment seems to us to be quite worth adding to this short note.

The precautionary measures recommended are ideal ones, theoretically, but may not be practicable in all instances, particularly in cases of small municipalities and where the work is purely of a temporary or an urgent nature. The uniform, recommended for all the workers, such as white putties, white trousers, white coat, white neck and face protector, white boots without laces and holes, and with elastic sides, is an elaborate one.

All that is necessary in the case of coolies employed in anti-plague work is (a) protection of workers by inoculation with anti-plague vaccine, (b) wearing of white overalls, and (c) smearing of the hands up to elbows and legs up to knee joints with kerosene-soap emulsion daily just before starting the work. These simple methods have been found to be quite efficient in practical work.

Risk from pneumonic plague infection is not great, at least in India.

Nowadays all cyanogas work in anti-plague campaigns is done with calcid briquettes. These can be used by men with some preliminary training and under good supervision without much risk, either to the workers or to the public. Gas masks are, however, still necessary if large rotary machines are used in this connection. This is rarely the case.

The shorter hours of work and frequent intervals of rest recommended are very useful suggestions.

The article as a whole is good and may be useful to those who are not in a position to read the instructions issued from time to time by some of those provincial and State governments to whom plague is still an important public health problem.—EDITOR, I. M. G.]

THE DISPOSAL AND UTILIZATION OF HORSE DUNG AND STABLE LITTER BY COMPOSTING

By K. A. PATWARDHAN, M.Sc.

Daly College, Indore, C. I.

Introduction

THE development of the Indore process to utilize as humus the waste products of agriculture in 1930-1931 by Sir Albert Howard and Y. D. Wad (1931) suggested its application to horse manure and stable litter, as a very desirable modification.

Such a modification will be chiefly suitable to the stables at the military stations in British India, and in Indian States and at the stables of other private individuals (owners of polo ponies and race-horses). The number of animals (horses and mules) in these military stables in India is over 50,000.

(Continued from previous column)

serological types.) The results furnished by Professor Schüffner are presented below :—

Strains	Agglutination titre of the patient's serum
90 C	3,000
Wijnberg	100
Canicola	100
Rachmat	0
Salinem	0
Sw. v. Tienen	0
Naām	30
Semarang 173
Batavia 46	0

3705	0
Sarmin
Moscou V	0
Andam. Ch 11	100
Hebdomadis	0
Ballico	0
Pomona	0
Benjamin	100
Djasiman	0

It will be seen from the above results that the infecting organism in this case is serologically homologous with a bat strain, inasmuch as the strain 90 C was recovered from the cerebrum of a bat (*Cynopterus*) in Batavia. This is the first time that a human serum gives a good reaction with this strain.

Summary

A new serological type of leptospira in the Andamans is recorded.

My grateful thanks are due to Major B. Chaudhuri, I.M.S., who sent us the serum and to Professor Schüffner and Dr. Gispén of Amsterdam, who carried out the agglutination tests referred to above.

REFERENCE

Taylor, J., and Goyle, A. N. (1931). Leptospirosis in the Andamans. *Indian Med. Res. Mem.*, No. 20. Thacker, Spink and Co., Calcutta.

Sanitary disposal of wastes from these stables is of the highest importance to all military establishments. At present the residues are sold at a rate varying between As. 6 to As. 7 per animal. The *gwalas* (Indian milkmen) usually purchase this material to feed their milch cattle with it. It is needless to emphasize how insanitary and dangerous this practice can be to the health of their customers, specially to the infant population.

A small stable usually with 8 to 10 ponies is maintained for the training of Kumars at the Daly College (a residential institution for the education of the sons of chiefs in Central India). This seemed to be a very suitable ground for a preliminary investigation into the possibilities of adopting the Indore process for the disposal

of garden sweepings and fallen leaves collected from the college compound. Wood ashes from the kitchens of the Kumars and ordinary black soil from the fields or dug out from the drains were also easily available. The trial started from October 1931 and compost has been regularly made since then up till 15th August, 1938.

The experience gained and its possible application to military and other stables is discussed below. Two sizes of pits have been used here, the length of the pit running across the prevailing direction of the wind, (1) 30 feet \times 14 feet \times 2½ feet and (2) 14 feet \times 10 feet \times 2½ feet. The available material (averaged for the whole period) worked out as follows (Table I), its chemical composition is given in Table II.

TABLE I
Raw materials annually available and compost made

Kind of raw material	Rates	Quantity of raw material used per year in lb.
Horse dung	* From 10 horses at 25 lb. (with moisture percentage 33.0) per head per day.	91,250
Litter	* From 10 horses at 15 lb. (with moisture percentage 20.3) per head per day.	54,750
Garden sweepings (air dry) .. .	At 3 cu. ft. per day and at 4 lb. per cu. ft. ..	4,380
Fallen leaves (air dry) .. .	At 3 cu. ft. per day and at 4 lb. per cu. ft. ..	4,380
Kitchen ash (air dry) .. .	At 30 cu. ft. per year and at 25 lb. per cu. ft. ..	750
Black soil (air dry) .. .	At 30 cu. ft. per year and at 70 lb. per cu. ft. ..	2,100
TOTAL WEIGHT OF RESIDUES USED		157,610 (i.e., 70.36 tons)

Total of air-dry compost obtained per year = 174.25 cartloads.
(Where 1 cartload = 20 cu. ft. and 1 cu. ft. = 25 lb.)
= 87,125 lb. (i.e., 38.90 tons).
Therefore percentage of compost obtained = 55.3.
* Average obtained from the record of six years.

Scope in military and other stables.—It is expected that 25 lb. of horse dung and 15 lb. of litter are ordinarily available every day for each animal housed in the military and other stables in India. Fallen leaves and other residues in the compound collected in the usual routine can also be utilized instead of being burnt; vegetable ashes and earth if available may be used but are not essential, as the natural properties of stable wastes enable them to be composted by themselves. Lieut.-Colonel T. M. Carpendale, C.-in-C. of I. S. A., has already successfully tried this process on a large scale.

The practicability of adopting this process under such conditions seems therefore to be clearly established. The 50,000 odd animals in these stables will yield about 892.8 tons of wastes, capable of producing 493.7 tons of compost per day, equivalent to an annual production of 180,290.5 tons worth about 4½ times as many rupees, i.e., at least Rs. 8,11,307-4.

The plant nutrients supplied by this quantity of compost will be equal to—

- (1) 937.5 tons of P₂O₅.
- (2) 1,171.9 tons of potash.
- (3) 1,478.3 tons of nitrogen.

In addition to an income of nearly Rs. 2,55,980 instead of Rs. 2,25,000 by the current method the further advantage of improving the sanitation of milk production in the areas will be secured, it being possible to feed the milk animals more efficiently and with greater safety with the fodder crops produced from the compost.

Acknowledgments

I am greatly indebted to Mr. M. G. Salter, M.A., Principal, Daly College, Indore, for the facilities and encouragement given and the keen interest taken in the work since its inception. I

Institute of Plant Industry, Indore, and Mr. Y. D. Wad of the Institute for giving me full facilities at the Institute for securing help and advice whenever needed. Thanks are also due to Major Johnson Cole, O.B.E., for getting for me the detailed figures from the Army Lists, showing the minimum computation of horses and mules and to Lieut.-Colonel T. M. Carpendale, Commander-in-Chief of Holkar State Army, for permitting me to refer to his successful attempts of adopting this process on a large scale.

A Mirror of Hospital Practice

AN INTERESTING CASE OF CHRONIC TETANUS

By P. N. KAPUR, F.R.C.P.E., D.P.H., M.R.C.S.
Divisional Medical Officer, N. W. Railway, Multan

THE following case seems worthy of note not only because of the survival of the patient after tetanus infection, but also on account of the comparatively rare mode of infection.

Mrs. X., aged 40 years, was admitted into the N. W. Railway Hospital, Multan, on 11th April, 1938. She complained of bleeding from the vagina for the past two weeks and difficulty in opening her mouth, for the past week. During this period of two weeks she was examined twice by a *dai*.

On admission, it was found that she was 3½ months pregnant and threatened abortion. She was put on bromide and chloral mixture and 3,000 international units of anti-tetanic serum were given.

On 12th April she had profuse bleeding and passed a portion of the foetus. Her uterus was emptied.

On 13th, she complained of pain and stiffness in the back of the neck and remarked that formerly she had

difficulty in opening her jaw, but now she was not even able to turn her head to one side or the other. She was x-rayed and the skiagram showed no evidence of pathological change in the temporo-mandibular joints nor carious teeth. An attempt was made to open her jaw under chloroform, but this met with no success. She was then diagnosed as a case of tetanus and was given immediately 8,000 units of anti-tetanic serum intramuscularly.

On the morning of 14th slight convulsion of her body began. The number of convulsive attacks during the day was not less than six and each attack lasted for a few seconds. She was given another injection of 8,000 units of anti-toxin.

On 15th the number of convulsive attacks was only two and the rigidity of the neck was slightly less. She was given another injection of 6,000 units of anti-toxin.

On the morning of 16th she was given another injection of 6,000 units of anti-toxin. By evening her condition showed definite improvement as the convulsive seizures ceased entirely and the stiffness of the neck lessened and the spasm of the lower jaw eased.

Her condition gradually improved and before her discharge from the hospital on 29th April, she was able to eat her ordinary food.

Comments

1. The disease appears to have been the result of infection through the vaginal mucosa caused by the introduction of sepsis as the result of examination by the *dai*.

2. The incubation period appears to have been under seven days.

3. The case belongs to the group of cases termed chronic tetanus.

4. The case was a typical one, as the chief symptoms were trismus, stiffness of the muscles of the neck and tonic spasm of the muscles of the trunk.

5. The course of the disease was practically apyrexial.

6. The absorption of anti-tetanic serum by the intramuscular method being slow, the maximum concentration of the serum in the patient's blood was not reached until 48 hours after the injection from which time the improvement started.

My thanks are due to the Chief Medical and Health Officer, N. W. R., Lahore, for having permitted me to publish this case.

COD-LIVER OIL TREATMENT OF A CARBUNCLE AND TWO ULCERS

By B. M. ROY, L.M.P.

Assistant Medical Officer, Nonapara Tea Estate,
Dimakuchi

Case 1.—A male coolie, aged 40 years, was admitted into the hospital on 9th November, 1936, for the treatment of a very extensive, ulcerated foul-smelling, non-diabetic carbuncle on his back. After incision cod-liver oil dressing was applied from the first day. For the first week the dressing was changed twice daily, then once a day. Complete healing took place in 19 days and the patient was discharged on 28th November.

Case 2.—A coolie girl, aged 14 years, was admitted on 23rd April, 1937, for the treatment of 'Naga sore' on her left leg. Cod-liver oil dressing was applied very thickly and was changed twice a day for the first six days, then once a day. The ulcer healed in 17 days

and she was discharged on 11th May, fit for work on the garden.

Case 3.—A male coolie, aged 26 years, was admitted on 18th July, 1937, for the treatment of a chronic ulcer

Fig. 1.—Case 1.

on the left leg, duration more than one year. He was also treated with cod-liver oil dressing in the same way as case 2 and the ulcer healed in 20 days.

In all these cases no other antiseptic dressing, tonic or injection to help healing was given except six grains of quinine daily.

Fig. 2.—Case 2.

Advantages of this dressing

(1) It is painless, both for application and removal of dressing; (2) slough disappears very quickly and removal of the same by surgical

measures is not required; (3) healthy granulation forms in a very short time; (4) patients like the oily application for which they themselves plead; (5) it is cheaper in comparison to other antiseptics.

Fig. 3.—Case 3.

I am grateful to Dr. E. Burke, my chief, for his permission to send these case notes for publication.

POISONING BY BITE FROM *BUNGARUS CAERULEUS* WITH RECOVERY

By A. R. D'ABREU, F.Z.S., L.M.S.S.A. (Lond.), I.M.D.
Civil Surgeon, Gujrat, Punjab

PYARE LAL, son of Subha Ram, age 22 years, of Nalagarh State near Simla, a juggler, had been in the habit of eating snakes. His performance consisted in biting off the heads of snakes at the neck, then chewing and swallowing them. His supply of snakes was obtained from snake charmers and he informed me that he did not know the difference between the poisonous and non-poisonous varieties but that he would depend upon the snake charmers to give him only the non-poisonous varieties.

At Kunjah, six miles from Gujrat, he did not find any snake charmers and he decided to find some snakes for himself. He came upon a dark steel-black snake about two feet long with regular white ringed markings all down its body. He controlled the reptile with a small stick and then caught hold of it with his hand about a span's length below the head, whereupon it immediately turned round and bit him on the hypothenar eminence of the right palm, he then let go his hold and had to shake the creature off which shows that the bite was a fairly sustained one.

This occurred at about 8 a.m. on the 24th July, 1938. He immediately sucked the wounds and tied a ligature round his wrist. He apparently felt no effects local or

otherwise during the morning or afternoon, but by 9 p.m. the same night he came to the civil hospital, Gujrat, with fully developed symptoms of colubrine venom poisoning. He could hardly sit up, streams of tenacious mucus were flowing from the corners of his mouth, the eyes were half closed, the face and lips moderately cyanosed, the tongue was only protruded with difficulty, he was conscious and had a peculiar indistinct slurring speech but was able to give a fairly good account of himself. Respiration was a little laboured, pulse fast and full and there was no rise of temperature. He was capable of moving the upper and lower limbs slowly to any position desired, tactile sensation did not seem impaired, the tendon reflexes were hardly elicited, the body was cold and there was great prostration. There was no swelling or pain about the two small punctures which were opened up freely and treated with potassium permanganate, as there was no anti-serum available.

PROGRESS OF THE CASE

25th July, 1938.—8 a.m. temperature 97.4°F.; 4 p.m. temperature 100°F. All symptoms were aggravated and the cyanosis of the lips and face was very marked and little hope was entertained for his life as asphyxia was increasing and he appeared to be sinking fast. There was now also difficulty in swallowing, pain was complained of in the abdomen and palpation elicited definite mild retraction of the rectus muscles but there was no tumidity, visible distension or dullness. Though lying in a very drowsy state he informed me between breaths and with great difficulty that he felt that air did not seem to get into his lungs. At 12 noon the pulse was 120 and respirations 48 per minute. At 12-15 in the afternoon 10 c.cm. of anti-serum C from the Pasteur Institute of Paris, which is labelled as specific against the venoms of *Naja* and *Bungarus* snakes of India and Egypt, was given intravenously. That is about 28 hours after the bite. At 9 p.m. the cyanosis had lessened a little and he said he felt better. The ptosis was the same and it was very difficult for him fully to open the eyes or look up. He took a little soda water and the salivation appeared slightly less. Atropine 1/100th grain was injected with good result on the excessive salivation. The pain and retraction of the abdominal muscles was about the same. There were moderate ronchi and râles all over the chest. The pulse was fairly full and regular from the time of admission.

26th July, 1938.—8 a.m. temperature 97.6°F. and pulse 96 per minute; 4 p.m. temperature 100.2°F. and pulse 130 per minute. Condition had generally improved and all symptoms were abating.

27th July, 1938.—8 a.m. temperature 102.4°F. and pulse 130 per minute. At 12 noon the temperature was still 102.4°F., with pulse rate 136 and respirations 52 per minute. When it was felt that all was going well it was discovered that pneumonic consolidation had developed at the base of the left lung. The patient became restless and vociferous but seemed mentally clearer and was losing his drowsiness. The drooping eyelids were about the same and the face slightly cyanosed and pinched. The temperature at 4 p.m. was 102.4°F., pulse 134 and respirations 48 per minute.

28th July, 1938.—8 a.m. temperature 100°F., pulse 112 and respirations 48 per minute; 4 p.m. temperature 100°F., pulse 122 and respirations 36 per minute. Appears weaker. He had been trying to sit up and walk in spite of warnings and restriction. Face drawn and pinched but mental faculties clearer. The drooping eyelids and drowsy appearance are passing away and salivation has ceased. Breath sounds of left lung hardly audible and there is no bronchial breathing or bronchophony, but dullness is present. The bowels are open and there is a strong desire for food.

29th July, 1938.—8 a.m. temperature 98.6°F., pulse 102 and respirations 28 per minute; 4 p.m. temperature 99.6°F., pulse 122 and respirations 28 per minute. The left lung has very slight dullness at the base and a few moist crepitations. A slight irritable dry cough is present, with whitish-yellow, frothy and partly sticky

expectoration. Heart sounds strong and pulse good and regular. There is no drooping of eyelids now but pain is complained of in the eyes. The tongue is moist and there is a strong desire for solid food. (The obvious clinical signs and symptoms of a pneumonia of the left lung which developed suddenly on the 27th July seem to have practically disappeared, this being the third day since these lung symptoms were observed.)

30th July, 1938.—S. a.m. temperature 98.2°F. and pulse 101 per minute; 4 p.m. temperature 99.6°F. and pulse 102 per minute. From this date onwards the patient rapidly improved and was discharged on 6th August.

He was shown my collection of Punjab snakes amongst which I had placed two specimens of *Bungarus caruleus* and on being asked to select the particular snake by which he had been bitten, he promptly pointed out these two kraits.

On interrogating this patient after recovery he stated that he had often been bitten by non-poisonous snakes and was also in the habit of allowing them to bite him for purposes of display in the presence of an audience.

It is probable that the hypothenar eminence of the palm of the hand having a thick epidermis and the fangs of a krait being comparatively small, penetration may not have been very effective the fangs only just reaching the verge of the vascular tissue, besides the punctures were immediately sucked.

In the literature on snakes, snake-bite and poisoning by the venom, authors consider the quantity of venom available in *Bungarus caruleus* as being about three lethal doses for man and that the virulence is about four or five times greater than that of cobra venom.

There appear grounds for assuming that the quantity of venom ejected by the *Bungarus caruleus* is comparatively small and for this reason it is probably a very potent poison even in minute quantities. The fangs of the blue krait are comparatively small and fine compared with those of cobras or vipers and, although the store of poison may be adequate, the jet of venom ejected must be a very fine one and therefore the quantity emitted during a bite comparatively less in the same way as we might compare the jet from the fine needle of a hypodermic syringe with that from a large bore one fitted to the same instrument, assuming the bite in most cases to be a very rapid or momentary process.

An examination of the fangs of *Bungarus caruleus* also reveals that they are frequently not completely tubular, this incompletely canalculated condition resulting in a groove on the anterior aspect of the fang may be due to imperfect development or insufficient age, and this imperfection would allow for leakage of venom along the fang in the reptile's mouth through the open segment of the canal.

Poisoning by the venom of the krait is generally considered to be most dangerous. From the literature accessible to me recovery from the

bite of a krait is rare, hence this case may be of interest to readers.

A RECURRENT STRANGULATED HERNIA INGUINALIS TREATED BY SECTION OF THE SPERMATIC CORD

By S. K. SEN, F.R.C.S.E.

Honorary Surgeon, Irwin Hospital, Delhi

and

R. H. CANDY

Lieutenant-Colonel, I.M.S.

Chief Medical Officer, Delhi Province

W. A., aged 50, male, was admitted to the Irwin Hospital on the 8th June, 1938, with a strangulated hernia presenting a typical picture of acute intestinal obstruction.

General condition on admission.—The patient was a thin-built adult with signs of leprosy. He had three fingers missing from the right hand and two fingers missing from the left, while there were areas of anaesthesia on both upper and lower extremities. His nasal discharge was examined bacteriologically but no lepra bacilli were detected.

The tongue was dry and coated and his pulse rate was 84 per minute. His temperature was normal. The abdomen was distended and very tender all over and there was a very tender and tense swelling in the right scrotal sac. The scars of three previous operations were present in the right inguinal region.

Previous history.—The patient was operated upon in Madras in 1932 for strangulated hernia on the right side, in 1931 he was again operated upon in Madras for a recurrence of the strangulation, and in 1935, in Calcutta, he was operated upon for the third time for a further recurrence of the strangulation.

The history of the present recurrence was of 24 hours' duration. The patient had had three vomits and complained of pain and swelling in the right inguinal region, with absolute stoppage of faeces and flatus for the past 24 hours. Shortly after admission the strangulation was reduced by taxis, after which the abdomen became soft, and faeces and flatus were passed freely during the ensuing two days. The internal ring at that time admitted four fingers.

Forty-eight hours later, the strangulation recurred and an operation was decided upon.

Permission was obtained from the patient for removal of the right testicle.

Operation notes.—On 11th August, 1938, the patient was operated upon under gas and oxygen anaesthesia. A liberal elliptical, transverse, incision was made to enclose the three previous operation scars which were then excised. The sac was isolated and opened and the loops of bowel were examined and replaced in the abdomen. The sac was then transfixed and the spermatic cord divided between two clamps at the level of the internal ring. The proximal cut end was ligated and sutured to the under surface of the internal oblique. The inguinal canal was radically closed by suturing the internal oblique and the conjoined tendon to Poupart's ligament with strong silk. The right testicle and the distal end of the spermatic cord were then removed and the wound closed in layers.

The patient made an uneventful recovery except that there was slight superficial sepsis at the medial end of the wound, which was detected when the first dressings were removed on the sixth day. The stitches were removed on the ninth day and the wound was perfectly healed.

on the twelfth day. The patient was discharged cured on the 39th day.

The reason he was not discharged earlier was that it was considered desirable to watch the patient as long as possible as there are no facilities of follow-up for the patient.

Remarks.—Burdick and Higginbotham adopted this drastic procedure of cutting the spermatic cord in 200 cases of recurrent inguinal hernia. They advocate that the testicle should be left undisturbed and in their experience it does not usually necrose. They reported 6 deaths in 200 cases and were able to follow up 169 cases, out of which there was a recurrence of the hernia in 20 (11.8 per cent). The testicle sloughed in four cases and suppurated in 17 per cent.

In this case the testicle was removed because of the high percentage of sepsis given in their figures.

Recurrent inguinal hernia is fairly common but the recurrence of strangulation is not at all common according to the experience of most surgeons. This case is of particular interest because of the fact that three previous herniotomies were performed on the same side and each time strangulation was present. The above operation of radical herniotomy was performed when the patient presented himself for the fourth time as a case of acute strangulation on the same side.

A CASE OF GUNSHOT WOUND OF LUNG

By B. S. MADAN, L.S.M.F.

*Sub-Assistant Surgeon, in charge, Civil Dispensary,
Mand (Baluchistan)*

J. B., a female, aged 30 years, was admitted into the dispensary on 29th May, 1938, for gunshot wound of the lung.

She was sitting on the floor and was shot from a distance of about 5 feet. The bullet passed through the body and entered the carpet.

The bullet entered the body half an inch to the right of the lateral sternal line in the 2nd inter-costal space, passed through the body and made its exit from the back $3\frac{1}{2}$ inches to the right of the post-median line in the 9th inter-costal space.

The wound of entrance was a quarter of an inch in diameter and wound of exit was three-quarters by half an inch. Both the wounds were almost circular and similar in appearance without any bruising or laceration of surrounding parts. There was only slight hæmorrhage. Temperature 100°F ., and pulse 120 per minute.

Wound of entry was painted with tincture of iodine and dressed with sterilized dressing. Wound of exit and its surroundings were cleansed (no fragments of bone were found) and wound was effectively packed. Morphia $\frac{1}{4}$ of a grain was injected to allay the nervous anxiety. Calcium lactate was given for five days afterwards. Dressing was renewed daily and the wounds healed without any difficulty and the patient was discharged on 25th June, 1938.

Points of interest are :

1. Patient was seven months' pregnant and did not miscarry after such a great and sudden shock.

2. Bullet passed straight through the body apparently without any deflection or deviation and without causing much damage.

My thanks are due to Lieut.-Colonel B. H. Kamakaka, I.M.S., for permission to publish this note.

A CASE OF CŒLIAC DISEASE

By NIHAR KUMAR NAG, M.B.

Bagerhat

A MALE child aged one and a half years was brought to me by his parents for diarrhœa with frequent offensive stools. The boy was healthy up to the age of 1 year but later on he began to pass diarrhœic stools which gradually increased. When he was brought to me he was suffering from diarrhœa and the stools were bulky and particularly offensive. There was loss of appetite.

History.—He is the first child of his parents, who are healthy. He was fed on artificial food from the age of nine months.

Examination.—The boy was markedly emaciated and anæmic. Wasting was most marked round about the buttocks. The face was very little affected. The abdomen was markedly protuberant and felt doughy. There was no sign of free fluid in the abdomen. The boy was very irritable. Growth was markedly below par. Liver slightly enlarged. Spleen not palpable. The boy used to pass about four to five stools a day which were large, pale, extremely offensive and frothy. Dentition was normal. There was no rickety rosary, nor Harrison's sulcus present. No enlargement of epiphyses was detectable. Blood examination showed marked anæmia.

The case was diagnosed as one of cœliac disease.

Treatment.—The treatment was mainly dietetic. He was given skimmed milk, about one quart a day, one over-ripe banana, and orange juice four ounces a day.

To prevent complications such as may occur from low fat diet, he was given Adexolin (Glaxo) 10 minims three times a day with milk. The boy improved gradually with this treatment and is now quite healthy except that he is slightly stunted in growth.

Comments

1. Cœliac disease is comparatively rare in Bengal.
2. It is very liable to be mistaken for rickets.
3. The treatment is easy and very effective.

[*Note.*—Cœliac disease is a clearly defined clinical entity in which there is, amongst other things, an increase of fat in the stools. In this case there were many symptoms suggestive of cœliac disease, but a more thorough investigation, including chemical examination of the stools, would have to be carried out to establish the diagnosis.

A condition similar to the one described is not uncommon in children in India; this condition responds well to a fat-free high-protein diet with an adequate supply of all the vitamins. Established cœliac disease is not usually so readily amenable to treatment.—

OUR DAILY RICE

NATHAN Gowland Hopkins, when in 1906 he foretold that there were many substances other than protein, fat, carbohydrate and inorganic salts essential to the maintenance of life, nor Casimir Funk, when six years later he invented that most attractive catchword 'vitamine', could have had any idea of the stimulus their work on this fascinating group of accessory food factors was to have on the whole study of dietetics throughout the world.

The wise physician has never underrated the importance of diet in the treatment of the sick, but at the beginning of the present century in western countries the field of dietetics, in as far as it was applied to the general supposedly-healthy population, was mainly left to food cranks, who were as wrong in most of their fads and fancies and in the baseless theories that they propounded as they were right in their insistence that more attention should be paid to diet, and to the occasional newspaper 'stunt' such as the eat-brown-bread movement of a quarter of a century ago. In eastern countries, and certainly in India, the main influence, other than economic and agricultural, in determining the diet of the people has been, and still is, ingrained custom supported by religious dogma.

In Europe and America the attitude of the man in the street to his diet has been entirely changed during the last decade; he has at least been made food conscious. The work of Hopkins, Funk, McCollum and other scientists has been carried on and enlarged upon by the advertiser and the columnist so thoroughly that the average individual has gained the impression that, if he were to take a number of pills containing the whole range of vitamins, he could dispense with proteins, fats and carbohydrates altogether. Even the medical profession has not escaped the over-emphasis on these very important, but still *accessory*, food factors; there are however signs that this phase is already passing and the interest aroused in the subject of food is being shared more evenly amongst the different constituents of a balanced dietary.

On the scientific side India has not been far behind other countries, but in this large and relatively poor country the time lag between the scientific appreciation of facts and the dissemination of the new knowledge amongst her 400 million inhabitants is considerable. A beginning has, however, been made, the medical man, the sanitarian and the social worker have little excuse if their knowledge on dietetics is rudimentary or out of date because during the last decade much work that is directly applicable to

the dietary problem in India has been carried out, and the results made easily available to any educated individual who has the desire to increase his knowledge. But the educated are only a small percentage of our vast population and the real problem is to carry the knowledge to the illiterate or barely-literate villager. Then, having carried this knowledge into the village, are we certain that it is going to be of any value? The answer is that, if it is the right kind of knowledge, it certainly is. It is, for example, no use telling the Bengal villager that rice is poor in certain constituents and that he must eat wheat, nor even that he should eat any particular kind of rice. He will have to be satisfied with the rice that he himself grows or the kinds that are available in the neighbourhood, and above all with the food that is within the reach of his very limited resources. But it is possible to tell him how he should prepare his rice so as not to impair further its nutritive value and how he can economically supplement his diet and supply some of the important food factors that are deficient in a pure rice diet.

Rice has come in for a great deal of ill-deserved abuse. Its defects are that its vitamin B₁ content is low, its protein percentage is distinctly below that of wheat, and it is deficient in calcium, with a disproportionately high phosphorus/calcium ratio. The vitamin B₁ is further decreased when the rice is highly polished or 'over-milled'. Over-milling also reduces the protein and fat content to an appreciable extent.

On the credit side we have the fact that the protein of rice is of a comparatively high biological value, distinctly higher than that of wheat for example, so that the lower protein content of the former is to a large extent compensated. In fact a good quality hand-pounded rice will have a biological protein value which, gramme for gramme, is very little short of that of an equal amount of wheat. Similarly, the vitamin B₁ content of hand-pounded rice is sufficient for normal requirements. This leaves only the calcium deficiency which must be made up. Amongst the cereals *ragi* millet is the richest in this substance; most of the pulses also have a good calcium content, but if economic conditions allow this deficiency cannot be made up more suitably than by the addition of milk to the diet. Further, rice is a fairly easily digestible substance if suitably prepared and it contains little indigestible cellulose matter. Its capacity for holding water in its cooked state makes it a very suitable food for a hot climate where a high fluid intake is a great advantage.

The fashion for eating milled rice was undoubtedly set by the upper classes to whom the clean shining highly-polished grain had an æsthetic appeal. Amongst people of this class who take a variety of other dietary substances to make up for the deficiencies, it is quite a suitable pabulum for the provision of calories, but the tragedy of this modern tendency was only appreciated when the practice was taken up by

the poorer classes in the community, who depend almost entirely on rice for their nourishment. Paradoxically, it is amongst the better class people that the disadvantages of milled rice are now appreciated; this has led them to demand hand-pounded rice with the result that the price of this commodity has risen correspondingly and is still further out of the reach of the poor.

This appears to provide an opportunity for useful legislation, but the problem is not quite as simple as it appears at first. Husked unpolished rice does not keep as well as does polished rice, on account of the presence of an enzyme in the outer coat of the grain that is capable of splitting the rice fat and turning the rice rancid. Times have changed and it is not always easy for people to go back to the old practice of each day pounding only enough rice for their daily needs. Machinery has come to stay and it is more in keeping with the times if, instead of trying to put the clock back, we attempt to advance further by standardizing machine milling and limiting the degree of polishing, and by studying methods of storing and preserving rice, or by encouraging the more extensive use of rice polishings as a supplementary dietary substance in the Indian household.

In a paper in our January issue Dr. Sreenivasan has discussed a number of points in connection with rice as a food, to some of which we have already referred. He has drawn attention to the fact that in the past agricultural experts have concentrated on producing rices with a high crop yield and of fine appearance. From the

producer's point of view both these qualities are desirable, but from the point of view of the consumer a rice with a higher protein content is what is required, and he considers that to achieve this should be the aim of agricultural research in India in the future.

Overshadowing all is the economic state of the country and the stark fact that a large percentage of the population has not the money nor the means to provide the minimum caloric requirements of the household, but this aspect of the problem is outside the scope of the present discussion.

As a sole article of diet rice, especially polished rice, is unsuitable, being deficient in certain important substances. As the staple article in a mixed diet it is excellent, for tropical climates, probably better than any other cereal in common use. It is possible that by legislation certain abuses in the preparation and marketing of rice which affect its nutritive value deleteriously could be prevented, and it is more certain that by agricultural research and judicious selection the quality of rice generally available could be improved. But the final solution of the problem is in the Indian home and the real responsibility rests with the Indian housewife, and those who educate and advise her. Except in the definitely indigent household, whatever rice is available the deficient substances can be provided at very little extra cost and appetizing dishes, representing a 'balanced' dietary, can be prepared to suit the tastes and pockets of each class.

'PATENT' MEDICINES, THE PUBLIC, AND THE DOCTOR

By E. S. PHIPSON, C.I.E., D.S.O., M.D., M.R.C.P.
COLONEL, I.M.S.

Inspector-General of Civil Hospitals, Assam

I. The nature and scope of the problem

MAN, even in his most civilized state, is a creature endowed with remarkable powers of credulity, powers which operate sometimes to his advantage but generally to his undoing, and in no department of life are these powers more manifest than in those matters which concern his bodily health.

In a recent lecture on the subject of Obscurantism in its many forms Lord Horder (1938) pointed out that even in highly civilized communities the mysterious form of cure often makes a greater appeal than does a plain and logical statement of how a given disease may arise from some particular departure from physiological rectitude, and how the trouble may be set right. 'What', asked Lord Horder, 'is the secret of the quack's success?' The answer he suggested is

that the patient is induced to think as follows: 'The quack is not trained and he is not recognized by law; how clever he must be to be able to cure people! His power is a direct and supernatural gift; a power which, on that account, must clearly be superior to even the highest skill which comes from a long and painstaking study on the part of the registered practitioner'.

In former days the quack was an itinerant vendor of his own nostrums, and his powers for good or evil were limited to the range of his own voice, and to such a *clientèle* as he could develop, in the towns which he visited, by favourable reports from the people among whom he moved. If he was a rogue, he was an amusing rogue, who lived by his wits, aided by a very useful and penetrating knowledge of human nature, and did very little harm. The pictures drawn by the American author, O. Henry, in *The Gentle Gaffer* of this type of quack, *Montague Silver* and *Jeff Peters*, were no doubt roughly applicable to the fraternity in all parts of the world.

The modern world, however, is very different, and a situation has arisen which deserves the serious attention of every thinking man and

woman. Throughout the United Kingdom, and to an ever-increasing extent in India, every man, woman and child, who can read, is constantly being subjected to the most skilful advertisement propaganda in newspapers, magazines, buses, hoardings, aeroplanes, stamps and the wireless (but not, fortunately, from Empire transmitters) designed and directed by experts in advertising on a scientific basis of applied psychology, with the single-minded intention of selling as much of a given product as possible for a given outlay on advertising—in the jargon of this very modern profession, 'overcoming sales-resistance', with complete and cynical disregard for the consequences to the unfortunate citizen whose 'sales-resistance' has been thus overcome, and who has been successfully persuaded that he is suffering from some disease, and must purchase the only effective remedy for it.

Some time ago the writer was called upon by the representative in India of a well-known preparation who asked the writer's opinion of his firm's product. The writer replied that he had a higher opinion of his firm's product than of their commercial morality. The representative showed pained surprise. This firm had within recent years, the writer explained, after half a century or more of blameless trading, embarked on a policy of intensive advertising designed to convince any person complaining of certain symptoms that he is suffering from a particular malady, and that if such a person takes this product for three months he will get well. The firm's representative, who was an agreeable and well-educated man, protested that he could see no indication of commercial immorality in this type of advertisement until the writer pointed out to him that the sufferer was subjected to a threefold suggestion: (a) that he was suffering from a particular malady; (b) that if he consulted a doctor (which he was represented as doing in the advertisement) this 'diagnosis' would inevitably be made by the doctor, who would order him to take the advertised product for three months, and (c) that he would recover as a result. The evil effect of these suggestions, the writer explained, was not that the sufferer was persuaded to take the firm's product for three months, which, indeed, might in itself be beneficial, but that of the wholly false suggestion that if he went to a doctor, complaining of that group of symptoms, the doctor would immediately and necessarily recognize them as indicating the minor disability suggested by the advertiser, and would prescribe the product accordingly. The symptoms complained of, the writer argued, might well be early symptoms of real and serious constitutional disease, and the sufferer, who might otherwise have sought medical advice, would be dissuaded from doing so by the advertisement and thus waste three precious months before obtaining proper diagnosis and treatment, a delay which might conceivably cost him his life, or, possibly, months or years of ill health. The firm's representative eventually

appeared to see the point and even promised to bring the matter to the notice of his Board of Directors!

The writer has related this story in detail to illustrate and emphasize what may well be regarded as one of the most sinister characteristics of the traffic in 'Patent' medicines, tonic foods and the like—the manner in which the wiles of the advertiser are used to exploit the credulity and the fears of the sufferer. The example quoted is not by any means one of the worst. Examples will occur to every reader of newspaper advertisements designed to induce every sufferer from dyspepsia to believe that he is suffering from gastric ulcer or carcinoma, every sufferer from chronic nasal catarrh that he is in the early stages of pulmonary tuberculosis and so on, and, by making capital out of the fear-complex induced in sensitive or neurotic persons, to secure them firmly as purchasers of the advertised product for as long as possible; and when it is borne in mind that in the daily press in England about one-sixth of all the advertising space is occupied by advertisements of proprietary remedies, and in the lower-grade weekly papers nearly one-third, it will be obvious that there must be very few sufferers from any common disease who are not constantly being subjected to suggestion from advertisements of this character.

II. Attempts to solve the problem

The whole question of the ethical and practical considerations involved in the patent medicine traffic has recently been summarized in a little monograph by Professor A. J. Clark, F.R.S., Professor of Pharmacology and Materia Medica in the University of Edinburgh (1938); the subject of quack medicines has recently been debated in the House of Lords after an admirable speech by Lord Horder, and in India it has been referred to by Colonel Chopra, Director of the Calcutta School of Tropical Medicine, as far back as 1923 in his Presidential Address to the Medical and Veterinary Section of the Indian Science Congress at Lahore, again in the Report of the Drugs Enquiry Committee and in his recent Presidential Address to the Annual Conference of the Bengal Pharmaceutical Association, reported in the *Statesman* of 13th September, 1938, which issue also contained an editorial on the subject which was very much to the point.

Professor Clark's monograph is a brief but comprehensive study of the whole problem as it presents itself in England, and the writer strongly recommends this small monograph to the attention of anyone interested in the subject. In the preparation of this article the writer has drawn freely on that valuable source of information, and on the Report on the Debate in the House of Lords (*B. M. J.*, 1938).

The attention of the medical profession and to a limited extent of the public was called to the question of the quack medicine trade by the publication of two volumes, 'Secret Remedies'

(1908) and 'More Secret Remedies' (1912), embodying the results of a long series of analyses of secret remedies carried out for the British Medical Association by the late Colonel E. F. Harrison, who, during the latter part of the Great War, was Controller of the Chemical Warfare Department of the Ministry of Munitions. These publications were received with great interest by the medical profession and the public but were practically ignored by the Press, presumably for reasons of policy.

In 1914, Parliament appointed a Select Committee on Patent Medicines which produced a compendious and very strongly-worded report and made some very practical recommendations regarding registration, disclosure of contents and censorship of advertisements, not one of which has since been adopted by Government. This report was unfortunately published on that tragic day, the fourth of August 1914, and received only a fraction of the attention it deserved, and would otherwise have commanded. There was no doubt of the Committee's views on the subject. Their general conclusions were as follows :—

'That the trade in secret remedies constituted a grave and widespread public evil; that the existing law was chaotic and had proved inoperative and that consequently the traffic in secret remedies was practically uncontrolled.

That this is an intolerable state of things and that new legislation to deal with it, rather than merely the amendment of existing laws, is urgently needed in the public interest'.

In 1917 Parliament passed the 'Venereal Disease Act' which forbade treatment of these diseases otherwise than by duly qualified practitioners, and expressly forbade the advertisements or sale of any remedies purporting to cure these diseases.

Another Bill dealing with patent medicines was introduced in 1931 without success, and again in 1936 a measure, with a very limited scope, designed to remedy some of the worst abuses of the trade, was introduced, but came up for second reading on the day of the Grand National, a circumstance which effectually sealed its fate as the House was 'counted out'.

With the sole exception of the very limited provisions of the Venereal Disease Act of 1917 the British law stands exactly as it did in 1914, when the Select Committee summed up the situation in the following words :—

'The situation, therefore, as regards the sale and advertisement of proprietary medicines and articles may be summarized in one sentence as follows :—

For all practical purposes British law is powerless to prevent any person from procuring any drug, or making any mixture, whether potent or without any therapeutical activity whatever (as long as it does not contain a scheduled poison), advertising it in any decent terms as a cure for any disease or ailment,

recommending it by bogus testimonials and the invented opinions and facsimile signatures of fictitious physicians, and selling it under any name he chooses, on the payment of a small stamp duty, for any price he can persuade a credulous public to pay'.

The medical profession as a whole is an uncompromising enemy of secret remedies, and as far back as the eighteenth century it was decided that it was unprofessional for a doctor to use remedies of whose nature he was ignorant or to keep secret the nature of the remedies he used, and these salutary principles still apply. Critics of the medical profession are apt, even in these days, to attribute the opposition of the medical profession to secret remedies to fear of 'competition', but as Professor Clark points out, there is nothing in this argument because secret remedies cause far more disease than they cure. While it is perfectly true as a general statement that doctors as a whole are opposed to secret and proprietary remedies, the statement requires some qualification for more than one reason.

Proprietary remedies, which include so-called 'patent' medicines (in reality a misnomer as no secret remedy can become the subject of a patent, and no new drug can itself be patented but only its process of manufacture), comprise a very wide range of medicaments, including some of the most valuable substances known to medical science as well as some of the most impudent frauds which are sold to the public. There are also the so-called 'ethical' proprietary medicines advertised (at any rate at the outset of their career) only to the medical profession by circulars, or through the medical press, as well as the 'non-ethical' group which are advertised to the public direct. Many doctors are in the habit of prescribing some proprietary mixture of known, or approximately known, composition, because it is more convenient or has some other desirable quality not possessed by a mixture made up by the local pharmacy. Even these preparations, carelessly used, can be dangerous particularly if they are in a concentrated form. The writer was once called to see the wife of his motor-driver, who was said to be possessed by a devil, but on whom the usual incantations had been found ineffective. It was evidently a case of strychnine poisoning, but the source of the poison could not be discovered until it was found that, a week before, the man had sent his wife to a dispensary doctor who had prescribed a well-known 'tonic' made by a firm of the highest repute. This 'tonic' contained a small dose of strychnine, about 1/120th grain to the drachm, and the patient had been told to take a teaspoonful three times a day. The patient being a Somali woman, and not knowing what a 'teaspoon' was, used the only spoon she knew of, which was of the hand-made African variety, fashioned out of box-wood and holding nearly one ounce, and, to ensure a more rapid cure, she had taken four

doses a day instead of three. She had thus taken about a quarter of a grain of strychnine every day for a week, when she started to develop opisthotonos. The dispensary doctor was surprised when the writer told him, in no uncertain terms, that, if she had died (fortunately she recovered), he would have been morally responsible for her death, for prescribing for an ignorant woman so potent a medicine in an undiluted form. Apart from proprietary mixtures there is also the group of 'household' remedies, the sale and use of which imply no danger to the public.

Thus, the best and worst are easily recognizable but the intermediate group are very difficult to classify from an ethical standpoint.

It is a somewhat humiliating, though perhaps a salutary, reflection that the medical profession as a whole is said to be as susceptible to suitably contrived advertisement as the general public, and the proof of this lies in the steadily increasing proportion of drugs prescribed in the United Kingdom, and doubtless in India, of drugs under proprietary names, which have non-proprietary equivalents which are equally good and much cheaper. Under the British scheme of National Insurance the proportion of drugs prescribed under proprietary names has risen to 30 per cent. The proprietary firm scores, the patient is no better off and the additional cost falls on the tax-payer.

III. Harmful effects of the patent medicine trade

The harm done by patent medicines, Professor Clark points out, may be considerable and sometimes direct in its operation. Fortunately the Dangerous Drugs Act prevents the sale in patent medicines of a number of dangerous drugs. There is with certain proprietary articles, such as medicated wines, more than a possibility of the production of addiction. The 1914 Committee mentioned 12 such wines with an alcoholic content varying from 16 to 21 per cent. These are said to find a ready sale among teetotallers who may perhaps be quite innocent of their alcoholic content, as, in some cases, no indication is given on the bottle.

Accidental poisoning sometimes occurs with the cheaper varieties of headache powders which contain acetanilide, a drug which is little used by medical men on account of its toxicity in some individuals. Attempts to reduce the manufacturing costs of patent medicines may lead to disaster; for instance, when one firm specializing in abortifacients substituted tri-cresyl phosphate for oil of apiol, an expensive commodity, a number of cases of paralysis resulted. Similar disasters resulted from the inclusion of amidopyrin in a proprietary yeast preparation, with several deaths from agranulocytosis as a result. Secret remedies for obesity containing di-nitrophenol have led to numerous fatalities, but both di-nitrophenol and amidopyrin have now been included in Schedule 4 of the Poisons List and

cannot be sold except on a medical prescription. One of the worst disasters of this kind was that which followed the introduction in America of a semi-'ethical' elixir of sulphanilamide, which is insoluble in water, but was found to be soluble in a solvent related to glycerine, di-ethylene glycol. The solution, in a given strength, was put on the market but without the nature of the solvent being disclosed. The comparatively small amount, 6 gallons, actually put on the market and consumed by the public ultimately caused no less than 73 deaths. *The Journal of the American Medical Association* commented on this disaster editorially as follows:—

'While it seems unbelievable that any manufacturer would circulate and promote the use of preparations for internal use without adequate preliminary tests of toxicity on animals and man this incident shows that it can be done.

Sixty persons have been sacrificed simply because the toxicologic observations now reported were not determined in advance by a manufacturer who had no hesitancy in importing physicians to use the elixir. Both chemical and medical literature contain references to the toxicity of di-ethylene glycol in the amounts recommended by the manufacturer.

Surely there has been no blacker picture of the inadequacy of our present food and drug laws or the lack of common scientific decency in drug manufacture than that illustrated by this tragic disaster'.

Although this happened in America, there is nothing whatever to prevent it happening in England or in India. The Poisons Acts always lag far behind advances in chemical and pharmacological research and though they can safeguard the public against scheduled poisons and drugs of addiction, they cannot legislate against drugs so recently discovered or, as in the case of di-ethylene glycol, so unexpectedly employed, that they have not found their way into the Schedule. One of the most sensational cases of poisoning in recent years was that of a Pittsburgh millionaire who died of radium-poisoning after having taken a 'patent' medicine for a number of years which actually did contain an appreciable quantity of a radio-active substance.

Lord Horder, in his speech before the House of Lords on 26th July, 1938, said that he had been warned that if he raised this subject he would be charged with trying to create a monopoly for himself and his colleagues, and to deprive the poorer classes of cheap cures, to the efficacy of which they constantly testify. Lord Horder maintained that if there was any question of monopoly it lay with the patent medicine trade which bled the British public annually to the extent of between £25,000,000 and £30,000,000, nearly as much as the total money spent on hospital services in England. In point of fact the debate in the House of Lords did produce in the daily press, as many will remember, a crop of letters denouncing Lord Horder in much the same terms as he had anticipated.

The main burden of Lord Horder's argument was the absurd and incongruous situation that had arisen. On the one hand the British Government had launched a campaign to improve the national physique, had recruited large numbers of people whose business it was to know something about health, had set aside subsidies for the purpose of education and demonstration in regard to fitness and had spent substantial sums of money in health propaganda. On the other hand they had this campaign of quack medicines and 'tonic' foods, totally uncombated so far by the Government, but led by very subtle and skilled generals, bent on maintaining national ill health, moral and physical, in order to have a ready sale for their goods. For every £100 that Government spent on making people health-conscious, quack medicine-mongers spent £1,000 on making them disease-conscious. The Government were trying to teach people the meaning of nutrition, and the money the people might spend on suitable food they were spending on quack medicines or on very poor substitutes for good food. If the State thought it right to protect the property of its less wary citizens by enacting legislation to limit the evil called 'share-pushing', was it not right to take measures to protect the health of its less wary citizens from wanton damage from clever and unscrupulous advertising propaganda in the field of quack medicines and 'tonic' foods?

IV. Proposed reforms

The three essential reforms proposed by the Select Committee in 1914 are set out in Professor Clark's book and are as follows:—

(1) Registration

'That there be established at the Department concerned a register of manufacturers, proprietors and importers of patent, secret and proprietary remedies, and that every such person be required to apply for a certificate of registration and to furnish (a) the principal address of the responsible manufacturer or representative in this country, and (b) a list of the medicine or medicines proposed to be made or imported'.

(2) Disclosure of contents

'That an exact and complete statement of ingredients and of the proportion of the same and every patent, secret and proprietary remedy, of the contents other than wine, and the alcoholic strength of every medicated wine, and a full statement of the therapeutic claims made or to be made; and a specimen of every appliance for the cure of ailments other than recognized surgical appliances, be furnished to the Department, such information not to be disclosed, except as hereinafter recommended, the Department to control such statement, at their discretion, by analyses made confidentially by the Government chemist'.

(3) Control of advertisements

'That it be a breach of the law to give a false trade description of any remedy, and that the following be a definition of a false trade description; "A statement, design or device regarding any article or preparation, or the drugs or ingredients or substances contained therein, or the curative or therapeutic effect thereof, which is false or misleading in any particular", and that the onus of proof that he had reasonable ground for belief in the truth of any statement by him regarding a remedy, be placed upon the manufacturer or proprietor of such a remedy'.

The Committee made a number of other recommendations. Amongst them was the following: 'That all advertisements of remedies for diseases arising from sexual intercourse or referring to sexual weakness be prohibited'.

They also recommend that advertisements likely to suggest that a medicine is an abortifacient be prohibited and that advertisement of remedies for the following diseases be prohibited:—

Cancer.	Diabetes.	Locomotor ataxy.
Consumption.	Paralysis.	Bright's disease.
Lupus.	Fits.	Rupture (without
Deafness.	Epilepsy.	operation or
		appliance).

The crazy inconsistency of the law is indicated by the fact that out of this long list of suggestions action has been taken only in a single case, namely, the prohibition of advertisement of remedies for venereal diseases. The success of this prohibition proves that such measures are practicable and effective.

Professor Clark recommends, and the writer agrees with him, that the disclosure of the contents of every proprietary remedy should be made not only to the Government Department concerned but displayed in intelligible terms on the label of each package.

V. The position in India

The time may come when some such restrictions will become law in India; the literate element of the Indian population are not so far subjected to such an intensive propaganda as are the people of England. In India the quack medicine advertisements in vernacular papers and papers printed in English are largely concerned with 'cures' for impotence and other sexual disabilities; they do not deal with ills of humanity as comprehensively as they do in England, nor do quack medicine advertisements in India comprise, except in a few papers of the baser sort, so large a proportion of the total advertisement-revenue as in England where, as we have seen, the proportion is from one-sixth to one-third of the total. It is perhaps worthy of remark that, no doubt as a result of the wide publicity given in India to the topic of tuberculosis in connection with Her Excellency the Marchioness of Linlithgow's Appeal, advertisements of a 'cure' for tuberculosis, which was

thoroughly discredited in England many years ago, are now appearing in many of the leading Indian newspapers. This cure was exposed in a British Medical Association Report, and also attacked by *Truth*. The proprietor was sued by a widow, and the judge stated 'I think this is an intentional and well-considered fraud. It is a scandalous thing that poor people should be imposed upon and led to part with their money, and to hope that those dear to them would be cured by those processes which were nothing but quack remedies, and had not the slightest value of any kind'. A few years later the proprietor sued the British Medical Association for libel but lost the case, and the remedy then disappeared from the market, as one would have hoped, for good.

Another preparation which made similar claims is also re-appearing, although it suffered the same fate; its suppression was accomplished in a unique and dramatic fashion. It first came into popularity during the influenza epidemic of 1918, as an antiseptic; then claims were made for it that the dream of *Therapia magna sterilans* had at last been realized, and that three pints of it would cure the most advanced case of pulmonary tuberculosis or any other bacterial disease. These claims were supported by an extraordinarily intense advertising campaign, full-page and even double-page advertisements appearing in practically every leading periodical in England in the summer of 1924, which many will remember. Almost alone among the British press, the *Daily Mail* refused to accept the advertisements but, on the contrary, published a three-column article by Sir William Pope, Professor of Chemistry in the University of Cambridge, denouncing the claims made by the proprietors as fantastic, and stating that the name 'tri-methenal allylic carbide', which was assigned to the 'active principle', was meaningless, gibberish and was not the chemical definition of any known substance. He concluded that the preparation consisted of—

'about 1 per cent of formaldehyde;
about 4 per cent of glycerine;
about 95 per cent of water;
and lastly a smell'.

The last constituent was perhaps to be expected as the preparation was said to be made from garlic. He calculated that the materials contained in a gallon cost about 1s. 6d., and the mixture was sold at £4-10-0 a gallon.

As Professor Clark states, the exposure, which many of us will remember, was completely successful, and the matter is of historic interest in that it is the only example of the career of a proprietary medicine being arrested by the action of the popular press, a Saul, indeed, among the prophets. Sir William Pope's article in the *Daily Mail*, in which he dealt with the claims of the preparation to cure such diseases as phthisis and cancer and other diseases for

which medicine knows no radical cure, included the following striking passage:—

'Phthisis (consumption) and cancer are among the most common of the diseases which fall into this category, and the secret remedy finds its greatest commercial success when offered as a specific cure for these maladies.

'Many of our poorer families include one or more members suffering from some mortal disease, and the utmost affection and care are often lavished upon these invalids.

'It is pitiable to think that people of this class, reading the warily phrased advertisements of a secret remedy, interpret them as guaranteeing a cure for the sufferer, and waste the money that is required for the mere necessities of life on useless and even harmful rubbish'.

VI. *The attitude of the medical profession in India*

What should be the attitude of the medical profession in India to the constant stream of tendentious literature that fills the postman's bag and to the cleverly presented advertisements that appear in the public press, and those which, most of them, of course, ethically quite unobjectionable, occupy so many pages of our favourite medical journals? Even Dr. Alfred Cox, late Medical Secretary of the British Medical Association, was constrained to admit before the Select Committee of the House of Commons in 1914, that the censorship of advertisements in the *British Medical Journal*, which should be above reproach, was not as discriminating as it might be.

As a profession—and this should be a sobering thought—it seems that, from the advertiser's point of view, we are not much less suggestible than the laymen; and that in spite of years of scientific study and of the practice of our profession, which should develop the critical faculty, we are unable to offer much more 'sales-resistance' to modern advertising in this field than the general public. Should we not make a determined effort to assess the claims of advertisers, contending for our support, in a more critical and scientific spirit, and, in the financial interests of our patients (or, it may be, of those of Government, or other employers), if for no other reason, show a little less readiness to prescribe or indent for proprietary preparations until we are fully satisfied that the corresponding preparations in their simpler and much less costly pharmacopœial form will not serve our purpose equally well?

Is there not a lesson to be learnt, for instance, from what must be a very costly campaign which is raging between the Dutch quinine interests and the German synthetic drug industry, each seeking to prove, by the free distribution of sumptuously produced literature, that their own product is the best?

The main protection of the public from exploitation must lie with the Legislature, and it

is to be hoped that a measure will be introduced before the problem has developed to unmanageable proportions, as appears to be the case in England, but there is much that we as doctors can do, by example and precept, to limit the effects of the tide of fraudulent misrepresentation which disfigures so much of modern commercial activity in the field of proprietary medicines and dietetic preparations.

The power of the press, in India, either for good or evil, is naturally limited by the extent of the literate population, but the *Statesman*—

all honour to that journal—has lifted its editorial voice, the writer believes for the first time in the history of Indian journalism, against the evils of the quack medicine trade. Is it too much to hope that other newspapers in India will follow the example?

Medical News

SUMMARY OF TUBERCULOSIS NEWS FOR THE MONTH OF DECEMBER 1938

Tuberculosis Health Visitors' Course

1. The first course for the training of female tuberculosis health visitors under the King George Thanksgiving (Anti-Tuberculosis) Fund starts from 16th January, 1939. Seventeen nominations were received through the provincial and state tuberculosis sub-committees, and ten candidates have been selected and will undergo training for six months at the Silver Jubilee Tuberculosis Hospital and Lady Reading Health School. Each candidate will receive a stipend of Rs. 20 p.m. with free furnished quarters. The employment and pay of successful candidates will be a matter entirely for the provincial anti-tuberculosis sub-committees who deputed them for the training.

King-Emperor's Anti-Tuberculosis Fund

2. The latest subscription list issued by the Honorary Treasurer shows that Rs. 66,84,515-7-5 were collected up to 13th December, 1938.

CONTROL OF DRUGS IN INDIA

EXISTING ACTS INEFFECTIVE

Stringent measures are needed to deal with the chaotic situation in regard to the profession of pharmacy in India and to the manufacture, sale and import of drugs in the British Pharmacopœia as well as those which are 'known and approved'.

The report of the Drugs Enquiry Committee in 1930-31 drew attention to the ineffectiveness of existing legislation to control the drug industry and prevent the sale of impure, adulterated and misbranded pharmaceutical products.

Mere adulteration of drugs is not, by itself, prohibited throughout British India by any enactment. Apart from the commission of the offence of cheating, adulteration which renders the drug 'noxious' or 'lessens the efficacy' or 'changes its operation' alone is controlled by the Indian Penal Code. Nor is the sale of a drug of insufficient strength or improper standard punishable otherwise than on the basis of misrepresentation and fraud. The non-existence of fixed standards or methods of analysis, the absence of any precise definition of adulteration, the difficulty of proof and the fact that intention or knowledge is of the essence of these offences, as well as of cheating, complicate the situation and render the provisions ineffective in practice.

In addition, false marks and false trade descriptions, the Marks Act and the Sea Customs Act merely touch the fringe of the problem of misbranding which is hydra-headed. Strict proof of difference in the nature or quality of the goods or the falsity of the description is often beset with impediments. The Cantonments Act is also of limited

scope and efficacy. The Indian Sale of Goods Act, 1930, which is merely concerned with obligations of a civil nature is also inefficacious in securing food and drugs of the opposite standard of strength, purity and quality.

As regards the profession of pharmacy, there are practically no restrictive laws of general application except certain perfunctory provisions in Municipal Acts of some of the provinces relating to the registration and licensing of retail shops and the employment of compounders.

VALUE OF INDIAN INDIGENOUS DRUGS

ONLY a very limited number of indigenous remedies deserve the reputation they have earned as cures and quite a large proportion of them are absolutely worthless and have probably crept in through tradition and folklore.

This is one of the results of an important research undertaken to investigate on scientific lines the claims of the rich materia medica of the Ayurvedic and Unani systems of medicine which was financed by the Indian Research Fund Association.

During the last twelve years this enquiry has done a considerable amount of work which has not only received local appreciation but international recognition. The Departments of Pharmacology and Chemistry of the School of Tropical Medicine, Calcutta, are now considered an authority on all questions in connection with the chemistry, pharmacology and therapeutic uses of the Indian indigenous drugs.

It has been found that many of the pharmacopœial drugs or allied species grown in India which could be used in the manufacture of pharmacopœial preparations are in common use.

SIXTEENTH ALL-INDIA MEDICAL RESEARCH WORKERS' CONFERENCE

VITAL problems affecting India's health were reviewed at the Sixteenth Annual Medical Research Workers' Conference which was opened by the Hon'ble Sir Jagdish Prasad, Member for Education, Health and Lands, in the Conference Hall of the Imperial Secretariat, New Delhi, on 12th December, 1938.

An unusually large number of medical and health interests were represented including administrative heads of Medical and Public Health Departments, distinguished members of the women's medical profession, representatives of the Indian States, military health services, railway medical organizations, the Rockefeller Foundation, the Indian Council of Agricultural Research, and others.

Remarking how grateful the Indian Research Fund Association and the delegates were to Sir Jagdish Prasad for finding time amidst his multifarious duties to be present, General Bradfield requested him to open the conference.

HONOURABLE KUNWAR SIR JAGDISH PRASAD'S SPEECH

'You have come here from various parts of India, some of you from the remote South, in order to apply yourselves to an extensive and formidable technical agenda', said Sir Jagdish Prasad addressing the delegates.

'Till last year this conference was held always in Calcutta and to some extent, therefore, functioned in a restricted orbit. I hasten to say, in deference to the feelings of any Calcutta person present, that I do not consider that great city a restricted spot in itself; what was in my mind is that the continued association of your conference with a single city in India had prevented the people of Northern India, for example, from having the aims and scope of medical research work in India brought more closely home to them. I think it has been a great benefit to have had it brought to Delhi, and I would be glad in due course if it could go the rounds of the main centres in India where those of your profession could conveniently gather and where they would find an appreciative local audience and co-operation. For the present, however, you are in Delhi and we are glad to have you here.

'I understand that it is no mere coincidence that during this week another conference is being held in Delhi, namely, that of the Association of Medical Women in India. A new and desirable innovation is that the delegates to the latter conference will be enabled to attend your morning sessions where they will have the benefit of listening to and taking part in your discussions.

'As you are probably aware, the Research Fund Association was founded in 1911 through the foresight of the late Sir Harecourt Butler, the first Education Member of the Government of India and one of the greatest Governors under whom it has been my good fortune to serve. He did many big things in a big way, and not the least of them was the foundation of this Association. Let us cherish his memory in grateful remembrance.

'The Association has produced one remarkable result during the comparatively short period of its existence', continued Sir Jagdish, 'namely, the training of a large number of Indian research workers of proved competence. Out of one hundred and six research workers paid by the Association no less than one hundred and three are Indians. In the Medical Research Department of the Government of India sixteen officers out of twenty-five are Indians. Research, therefore, is now predominantly in the hands of Indians, and they are the inheritors of a great tradition. Medical research in India has many achievements to its credit, specially the notable contributions it has made to our knowledge of kala-azar, malaria, plague and cholera. Prolonged research discovered the probable carrier-agent of kala-azar and produced a method of mass treatment which practically stamped out the disease in its chief home, Assam. The efficacy of our prophylactic anti-cholera and anti-plague vaccines is now generally recognized. Though much work of world-wide recognition has been done in regard to malaria, it is still one of our most formidable enemies and continues to take a heavy toll of life and to sap the energy of a vast number of our people. While we are proud of our achievements we cannot yet say, as for instance it can be said of England, that cholera, typhus, typhoid, plague, smallpox and malaria have been stamped out.

'There is still a wide gap in this country between the results of research and their successful practical application. Poverty, ignorance and prejudice among the masses, a certain scepticism as to the results of medical research among the educated classes, with a consequent absence of continuing pressure of public opinion on Governments for effective measures against diseases, are some of the many causes which seem to make India the prosperous home of so many human scourges. In no country, except perhaps China, is the need for continued research and its practical application so insistent as in this country where life is often an uninterrupted gamble in disease. The prevalence of such a distressing variety of deadly human ailments

in this country probably accounts for some of the deep pessimism and fatalism that pervades Indian thought. The sorrow and deep tragedy of life, rather than its joy and brightness, obsess the mind. Such an attitude numbs initiative and deadens the effort to make life worth living.

'In my view nothing is more likely to stimulate public opinion and to make it realize the extent to which organization under scientific direction can be effective, than the eradication or control of even a single disease in a specified area. If we can free even one infected town of, say, malaria, we will have made a great advance in the education of public opinion. From this point of view the intensive and hitherto successful campaign against malaria in Delhi is of more than local importance. It not only brings the results of research, as it were, from the laboratory to the market place, but, what is more important, it produces a healthy change in the attitude of the people in regard to the effectiveness of modern public health methods. I am sure that if we could say with confidence that we had completely freed Delhi of malaria and had made Simla safe for those who are now drawn there more by the force of circumstances than by reason of its reputation for salubrity, we should have done much to bridge the gap between medical research and its successful application to the lives of the people. We should have taken a big step forward to convince doubting men and women that there could be no more suitable object of public benevolence than the endowment of medical research.

'Without the aid of public benefactions I fear that, with our present financial resources, the provision for medical research must remain inadequate for many years to come. In comparison with Western countries our expenditure on research is meagre and there seems little prospect of improvement in this respect in the near future. At the same time I fully recognize that it would be short-sighted policy if violent budgetary oscillations were to result in throwing out of employment a number of workers engaged in important work and in the prime of their powers. Such a policy would indeed give a serious set-back to research in India and will, I hope, never find favour.

'While I am on this subject of research I should like you to remember that in a poor country like India it is not enough to discover a remedy. If it is to be widely adopted it must be within the means of the Governments and peoples to apply. To give an illustration, the efficacy of quinine in the treatment of malaria is recognized. We all know, however, that at present prices quinine can be used by only a very small fraction of the population. Research must, therefore, continue into remedies both preventive and curative which may be within the financial resources of the country. In India the research worker cannot ignore the economic conditions of the people for whom his researches are primarily meant.

'It will be generally admitted that some of the fundamental causes that produce ill health, such as poverty, overcrowding, defective sanitation and water supply, evil social customs and ignorance of the laws of health, are outside the immediate field of your work. Your primary concern is, I take it, with the causation, prevention and cure of human diseases. Your object is to save human life and to alleviate human suffering, in contrast to some researches in other realms of science where new discoveries seem to threaten the very existence of civilization as we know it.

'I do earnestly pray that no diabolical ingenuity may ever pervert the discoveries of medical science to the destruction of mankind. It is my earnest hope that by your continued researches you may place at the disposal of the men and women of this country and of their Governments powerful weapons with which to destroy the long and desolating supremacy of disease and preventable death in this country and to secure for the people of India the inestimable blessings of health and physical fitness.'

General Bradfield addressing the delegates said he joined with the Hon'ble Member for Education, Health and Lands, in extending to them all a hearty welcome

to Delhi. The holding of the conference in Delhi last year had to some extent been an experiment, but the general satisfaction expressed by the delegates had encouraged the Scientific Advisory Board to suggest Delhi for a second time. By the end of the week, a decision would have to be made regarding arrangements for next year. They had anticipated the desire expressed by Sir Jagdish Prasad to see the conference held in different large centres in India, for he understood that their fellow workers in Bombay and in Madras had already made certain suggestions in that respect. These would be considered before a final decision was reached.

WOMEN DELEGATES

Looking through the list of delegates, the Director-General said he had been struck by the wider number of medical and health interests represented as compared with earlier conferences. It was a great pleasure to have again the assistance of distinguished members of the women's medical profession, and a welcome innovation would be the attendance at their morning sessions of delegates from the Annual Conference of the Women's Medical Association of India, which was also being held in Delhi during the week. He felt sure that they would find many of the discussions both interesting and profitable.

Indian States were represented by ten officers of whom nine received a special training in nutrition survey work at the Coonoor Laboratories during the early months of the year. They were glad, continued General Bradfield, that the States in question recognized the importance of the Indian Research Fund Association and realized the benefits to be derived from making contact with its activities. He welcomed representatives of the Rockefeller Foundation whose presence indicated the continued interest which the Foundation took in the promotion of public health, and Mr. Knipe and Mr. Dyer, whose special knowledge of sanitary engineering in general and anti-malaria engineering in particular would undoubtedly be of great value to health administrators in this country. By their assistance in promoting measures for the improvement of the health of the rural population, the work of the Rockefeller Foundation had made a definite impression on the public health of India, which would, he felt certain, prove of lasting value to progress in that field.

MILITARY HEALTH SERVICES

The presence of representatives of the highly organized military health services reminded them, he stated, that the health problems of the military and civil populations in India converged so closely in many places that only co-operative action could ensure success. The necessity for that co-operation was well recognized both by military and civil administrators, and its further development would be discussed at the forthcoming meeting of the Central Advisory Board of Health.

The Indian Council of Agricultural Research, whose nutritional and other activities in the fields of agriculture and animal husbandry were so closely allied to their own, were represented this year by Mr. Kerr whom, said General Bradfield, they were glad to welcome particularly as that was the first occasion he had attended their conference.

The increased representation of the railway medical organizations on the occasion was gratifying to them all, and the Director-General assured Dr. Cairns and his colleagues that they welcomed their participation in the discussions. The railway medical organizations in this country were large and important and, as in the case of the military authorities, their co-operation in the field of public health was of vital importance.

The railway authorities had further contributed towards making the conference a success. General Bradfield referred to the generous action of the Railway Board in arranging that their delegates should be given the benefit of Christmas concession fares at a date considerably earlier than that on which these were ordinarily made available. This had enabled the

presence of a number of research workers who might otherwise have found it impossible to attend.

RESEARCH AND FINANCE

In discussing the affairs of the Indian Research Fund Association, its research activities during the present year and its plans for the coming year, he said he apologized if he had to open on a depressing note. But he felt it his duty to bring to their notice at once that, contrary to expectation, the financial position of the association, which had been a cause of anxiety to both the Governing Body and the Scientific Advisory Board for some years, had not improved. Since 1932 the activities of the association had been maintained at their present level only by drawing on capital funds, because the Government of India had been unable to give an annual grant larger than Rs. 1,50,000, compared with its previous grant of Rs. 7,50,000. It was hoped that this drain on the capital of the association would be appreciably reduced during 1938-39 by the Government of India undertaking responsibility for the Public Health Section of the Malaria Institute of India. Unfortunately, this hope had not materialized and the Governing Body had been compelled to draw further on its capital to the extent of Rs. 4,50,000.

These facts were mentioned, the Director-General continued, so that they would appreciate the necessity for close scrutiny of the proposals for next year's programme. After the unfavourable financial position revealed itself in April last, the Executive Committee of the Governing Body was compelled to consider whether some, if not all, of the newly sanctioned researches should not be cancelled. Any such step would have meant the postponement of important investigations, and would have resulted in disappointment to those workers who had convinced the Scientific Advisory Board of the merits of their particular proposals and who, in some cases, had already engaged their staff. The Executive Committee, therefore, came to the conclusion that whilst sanctioned researches should be allowed to continue, the officers in charge should be required to limit their expenditure to absolute essentials.

PROVINCIAL RESPONSIBILITY

The number of enquiries being conducted this year, explained General Bradfield, was 63 compared with 53 in 1937-38 and with an average of 38 during the five preceding years. Applications had been received for the continuation of 56 enquiries and for the inauguration of 22 new enquiries, or 78 in all. It would be necessary to examine every proposal with the greatest care, but the Scientific Advisory Board and the Governing Body would, as usual, give full consideration to their discussions and to the recommendations made by the conference.

The grants given during the present year, stated the Director-General, numbered 42 to laboratory enquiries and 20 to field enquiries. Nineteen of the enquiries were in medical colleges or schools. He drew attention to a matter which, he believed, was not as fully appreciated as it might be. Whilst the Indian Research Fund Association had always considered applications for grants from medical colleges, it should be remembered that modern practice assigned a definite responsibility for research, and more particularly for investigation into problems of local interest, to teaching institutions, which should be provided with the scientific equipment and staff to undertake them. As evidence of their active association and sympathy with the ideals of this conference they appreciated the attendance of a number of representatives of medical colleges, many of them old friends. Their research activities called for their sympathy, but they should also look for encouragement from the governing authorities of their own colleges and seek financial support from their Provincial Governments.

COMMITTEE'S REPORT

Referring to the committee of six which the Governing Body had set up to enquire into the conduct of medical research under the Indian Research Fund

Association, General Bradfield said that the sub-committee, after preparing a preliminary draft earlier in the year, had met last week to adopt the final form of its report to the Governing Body. All that it was possible for him to say at the moment was that the committee had taken a broad view of its terms of reference.

During the year six officers were recruited to the Medical Research Department, including one for special research in malaria. Four had already joined and the others were expected to do so shortly. The Director-General trusted that these new recruits would make every effort to maintain the high standard which had in the past characterized the activities of that Department.

In a resolution passed at last year's conference regarding the necessity for placing adequate and cheap treatment of malaria within the reach of the people, continued the Director-General, they noted that the Government had instituted an enquiry into the possibilities of extending the cultivation of cinchona in India. The report of the special officer appointed to conduct that enquiry was now in the hands of the Imperial Council of Agricultural Research. The completion of this enquiry was an important step towards ascertaining the possibility of making India self-supporting in the matter of its quinine requirements.

CHOLERA DANGER

General Bradfield made special reference to the question of cholera. The great danger, he said, which this disease continued to present in India was illustrated last spring when, as a sequel to the large melt held in Harwar, an epidemic broke out and spread over wide areas of the country. The administrative control of these outbreaks would be more suitably discussed at the Central Advisory Board of Health meeting which was to be held early in January. At this Research Conference they were more concerned with the efforts being made to elucidate the causes of such regrettable outbreaks and they would be able to assess the results achieved by the enquiries which had been in progress during the last five years.

Owing to the uncertainty which existed in regard to the relationship between the cholera vibrio and other vibrios, and in regard to the serological differentiation of different types, the International Office of Public Health in Paris had decided that special investigations on these questions were urgently necessary. As a result of earlier work, it had been made evident that many points could only be cleared up by research carried out in endemic and epidemic cholera areas and India was asked to undertake this work. Owing to the nature of the problem the work in India had naturally fallen into two phases, one laboratory investigation and the other conducted in the field. The phase of laboratory investigation had involved the collection and detailed examination of some thousands of vibrio strains from cases of cholera, from carriers and from water. Their work had proved that vibrios of many different types were widely distributed in nature, but by the adoption of new serological methods, the true cholera vibrio could now be differentiated from other types, whose presence in water supplies and human carriers had in the past led to much confusion.

FIELD INVESTIGATIONS

With a new and reliable basis for the diagnosis of the cholera vibrio and with more accurate knowledge of the distribution of other types the Director-General said they were now in a position to undertake on an effective basis the second phase of the enquiry, namely the field investigation of the factors concerned in the epidemiology of cholera and particularly those concerned with its persistence in certain endemic areas. The Cholera Advisory Committee would, therefore, be asked to discuss a proposal to terminate the enquiries of an essentially laboratory nature and to concentrate on field work in endemic areas such as were to be found in Bengal and Madras.

The work so far done had been undoubtedly productive and its value had been warmly appreciated

by the International Office of Public Health. The Cholera Commission of that body in its report of May 1938 recorded its acceptance of the findings made in India which had answered the questions put forward by them in May 1934. Throughout these investigations close association had been maintained with workers of the Medical Research Council in England and it was hoped shortly to present a full and co-ordinated account of this work.

NUTRITION

Turning to nutrition, General Bradfield said that further progress had been made during the year. A training course for health officers in public health nutrition work, including methods of carrying out diet surveys, was held at the Nutrition Research Laboratories, Coonoor, in February and March last. Fifteen officers attended, twelve being from Indian States and the remaining three from Delhi, Orissa and Sind respectively.

Satisfactory publicity had been given to recent work of practical value to India by the issue of a health bulletin entitled, 'The Nutrition Value of Indian Foods and the Planning of Satisfactory Diets'. To increase the circulation of the important information contained in this bulletin, the Government of India had agreed to issue it at the specially low price of two annas. Nearly 25,000 copies had been sold. An up-to-date and enlarged edition was in the press, and an important improvement, which made the bulletin of greater value to the layman, was the inclusion of Indian names for the different foods.

Last year the Nutrition Advisory Committee emphasized the finding that skimmed milk was of great value in improving the health and development of Indian children and recommended that milk powder containing not more than 4 per cent of fat should be exempted from customs duty. This recommendation, he said, had been accepted by the Government of India, so that imports of skimmed milk from Great Britain were now free of all duty whilst the duty on that from other countries had been reduced to 10 per cent.

The important Conference of Far Eastern Countries on Rural Hygiene held in Java in 1937 recommended the establishment of a National Nutritional Committee in each country. The Government of India had accepted this recommendation and had decided that the Nutrition Advisory Committee of the Indian Research Fund Association should perform the functions of a National Nutrition Committee for India.

The value of the work done under the auspices of the Association in the matter of nutrition and the high esteem in which the Association's Nutritional Laboratories at Coonoor were held by Eastern countries, had been indicated, continued General Bradfield, by a request from the League of Nations Health Committee that the Coonoor Laboratories should assume the task of co-ordinating nutrition research in the East. This request would come before the Governing Body for consideration at its next meeting. In March last, the Governing Body had given sanction to the acceptance by the Director of Nutritional Research of membership of the League's Technical Commission on Nutrition. During his leave this summer, Dr Aykroyd attended a meeting of this Commission.

MALARIA

Regarding their malaria organization, he stated that disappointment was experienced when the Government found it impossible for financial reasons to take over the Public Health Section of the Institute, an important element of which was the Field Experimental Station at Karnal. In 1936 this conference had recommended that the Experimental Station should be transferred from Karnal to Delhi at the earliest possible date. There were obviously desirable reasons for making such a move. In the first place, it brought this important field unit into closer contact with the general public and with irrigation and other engineers. Moreover, a valuable museum had been built up at Karnal, but its remote situation was a serious handicap to its

usefulness. The Government of India had agreed this year to give Flagstaff House in Old Delhi to the Association for housing the Field Experimental Unit and the transfer from Karnal to Delhi was now in progress. In addition, the annual malaria classes would in future be held in Delhi where the anti-malarial schemes now more or less completed would constitute an excellent demonstration of the value of anti-malarial schemes based on sound knowledge.

YELLOW FEVER

Last year he had made a brief reference to the danger of the introduction of yellow fever into India owing to the rapid development of air transport. On two previous occasions at these conferences General Graham, the late Public Health Commissioner, made a statement on the position as it then stood. An important part of their preventive organization was the arrangement under which the Sanitary, Maritime and Quarantine Board of Egypt not only kept them informed of the movements of suspected passengers proceeding to India but also took steps to destroy mosquitoes which might be present in suspected aeroplanes coming to this country. Colonel Russell had visited Egypt last spring and later in the conference would give them a description of the present epidemiological features of this disease and the preventive measures now taken in this country against possible introduction of infection.

After his visit to Egypt, Colonel Russell had also discussed the subject with representatives of air lines in London and later attended the May meeting of the International Public Health Office in Paris. He was able to present papers from Indian Research Fund Association workers on the following subjects: cholera, nutrition, quinine, post vaccinal encephalitis, the population problem, and tuberculosis. General Bradfield said they had been assured by the Director-General of the International Office in Paris that the papers contributed by India were received with deep appreciation, and there was no doubt that the prestige of their medical research workers stood high in international circles. That position could only be maintained by careful thought, sound judgment and hard work and the Director-General hoped that it might be possible to continue to show to the world in general that India and her research workers were determined to maintain their leading place in the field of humanitarian and scientific endeavour.

LEPROSY CONFERENCE

During the year an International Conference on Leprosy had been held at Cairo and India had sent seven delegates. The report of that conference went to show that the anti-leprosy work in India had been planned on sound lines. In September, an International Conference on Tropical Diseases, with special reference to Malaria, had been organized by the Dutch authorities at Amsterdam. The Government of India had sent two delegates, but unfortunately the international crisis in some measure detracted from what otherwise would undoubtedly have been a profitable and interesting meeting. The Government of India were also represented at the International Entomological Congress held recently in Berlin.

The Central Advisory Board of Health, he stated, would hold its next meeting in Madras on 9th and 10th January. Those who were concerned with maternal and child mortality would learn with interest that the special committee appointed by the Central Board to report on Maternity and Child Welfare in India had completed its task. Many of the administrative officers who were present would no doubt be present at the meeting in Madras and he recommended to their serious attention the Committee's report and the four memoranda which dealt with the other items on the agenda.

A PRIMARY CONSIDERATION

General Bradfield concluded by impressing especially on the younger workers that, when choosing a subject for research, they should always keep in mind the

importance of its applicability to the improvement of the health of the people in India. This must always be a primary consideration with the Scientific Advisory Board in making their recommendations to the Governing Body. Scientific research was a matter to which considerable importance was attached both by Governments and the public. Their deliberations last year were the subject of wide interest and the valuable contributions made by workers in India to knowledge of disease were given much favourable comment both in the press and elsewhere. He was confident that their discussions this year would be equally helpful and stimulating.

OVERCROWDING IN INDIAN MENTAL HOSPITALS

Overcrowding, with its implications of growing hardship to the patients and increasing difficulties for the institutions, is reported in India's mental hospitals. With increasing urbanization and education there is a greater demand that these patients should be cared for and that institutional treatment for the indigent mental patients should be a charge on the State.

At present there are only 17 mental hospitals in British India—three in Madras Presidency, five in Bombay Presidency, three in the United Provinces, two in Bihar and one each in the Punjab, Central Provinces, Assam and Sind. The province of Bengal has arrangements by which its mentally defective patients are admitted to the mental hospitals in Bihar. There are no such hospitals in Orissa or the North-West Frontier Province.

Among States, Mysore has a mental hospital at Bangalore, with accommodation for 183 males and 67 females, and Hyderabad has a small mental hospital in the central jail. A scheme for the construction of an up-to-date mental hospital has been sanctioned and the work is to be started shortly.

In the 17 hospitals in British India there is accommodation for 8,425 patients, but the number of patients actually confined in these institutions in 1936 was 11,792 of which 8,930 were males and 2,862 females. There was overcrowding in almost all the hospitals, but it was more acute in Madras, Bombay and the United Provinces. The demand for admission in some hospitals was so great that even criminal insanes had to be lodged in jails where there was no satisfactory arrangement for treatment.

Psychiatric clinics.—A greater part of the accommodation in the existing mental hospitals is occupied by incurable patients, and the only important advance made in recent years has been the organization of psychiatric clinics at medical teaching institutions in Bombay, Bengal and the United Provinces. No such clinics exist in the Punjab, Bihar, Central Provinces and Berar, Assam, North-West Frontier Province, Orissa, Baluchistan and Coorg. Funds are not available anywhere to provide adequate accommodation for mental patients, but whenever possible psychiatric clinics should be opened at the larger hospitals. Such clinics deal especially with the early curable cases and when combined with a neurology clinic often produce the confidence which attracts patients.

Mentally defective children.—Another pressing problem is the provision of separate institutions for the training of mentally defective children. In Madras a class of about 15 children, who were inmates of the Madras Mental Hospital, was formed in 1937 and instruction in sense training, simple story-telling, picture-drawing, etc., was given and facilities for excursions, outdoor games, amusements and certain simple cottage industries provided. In Bombay the training is given at the Byramjee Jeejeebhoy House for Children, Matunga, which is maintained by the Society for the Protection of Children in Western India. The children are taught on Montessori lines and the training includes classes on sewing, embroidery, raffia work and thread work. Mentally defective children in Bengal are treated at two private institutions.

No facilities for the training of such children exist in the United Provinces, the Punjab, Bihar, Central Provinces and Berar, Assam, Sind, North-West Frontier Province, Orissa, Baluchistan and Coorg.

Causes of insanity.—Among the predisposing causes of insanity, judged from the conditions of admissions during 1936, were mental and moral stress, business and domestic worries, addiction to drugs and drink, infections, previous attacks and hereditary predisposition. The largest number of cases was between the ages of 20 and 40. Out of a total of 11,798 cases of insanity in 1936, 839 were due to mental deficiency, 1,187 to maniacal depressive insanity, 1,919 to mania, 1,441 to melancholia and 2,195 to schizophrenia including dementia praecox.

BIRTH-CONTROL RESEARCH COMMITTEE OF VILE PARLE

THE Secretary, Birth-Control Research Committee of Vile Parle, has supplied the following information:—

The number of people who visited and sought advice at the Birth-Control Centre at 166A, Vincent Road, Dadar, Bombay, conducted by the Birth-Control Research Committee of Vile Parle, during the quarter ending 15th December, 1938, was 925 out of which 512 were males and 413 were females. This quarter completes the first year of the existence of this centre and the total number of people who visited during the period was 2,165.

THE INDIAN HONOURS LIST

2ND JANUARY, 1939

THE following are the names of medical men, and others, associated with medical institutions, in the Indian Honours List of date 2nd January, 1939. We offer them our congratulations.

Knighthood

Colonel A. J. H. Russell, C.M.E., R.H.S., I.M.S., Public Health Commissioner with the Government of India.

Colonel K. V. Kukday, C.I.E., I.M.S. (retired), Central Provinces and Berar.

C.I.E.

Major-General N. M. Wilson, O.B.E., I.M.S., Surgeon-General with the Government of Madras.

Lieutenant-Colonel J. B. Hance, O.B.E., I.M.S., Residency Surgeon in Mysore, Bangalore.

Lieutenant-Colonel G. Covell, I.M.S., Director, Malaria Institute of India.

Lieutenant-Colonel E. W. O'G. Kirwan, I.M.S., Professor of Ophthalmic Surgery, Medical College, Calcutta.

C.B.E. (Civil Division)

Dr. Charlotte Leighton Houlton, Chief Medical Officer, Women's Medical Service, India.

O.B.E. (Civil Division)

Miss Ethel Adelaide Douglas, Missionary doctor in charge, Lady Kinnaird Women's Hospital, Lucknow, U. P.

Lieutenant-Colonel K. R. K. Ayyangar, I.M.S. (retired), lately Director, Pasteur Institute of Southern India, Coonoor.

Major D. P. Bhargava, I.M.S., Professor of Surgery, Prince of Wales' Medical College, Patna.

M.B.E. (Civil Division)

D. C. Chakravarti, Esq., V.H.S., Bengal Medical Service, Professor of Clinical and Operative Surgery, Medical College, Calcutta.

R. T. M. Hayter, Esq., I.M.D., Assistant Director, School of Tropical Medicine and Resident Medical Officer, Carmichael Hospital, Calcutta.

Captain H. D. R. Zscherpel, I.M.S., Superintendent, Central Jail, Peshawar.

Kaisar-i-Hind Medal (First Class)

Mrs. Sivakamu, Principal Zenana Medical Officer, Bikaner State, Rajputana.

A. D. Miller, Esq., Secretary, Mission to Lepers, India, Bihar.

T. H. Somervell, Esq., in charge of the London Mission Hospital, Neyyoor, Travancore State, Madras.

Bar to the Kaisar-i-Hind Medal

(First Class)

Miss Ida Sophia Scudder, Principal, The Missionary Medical College for Women, and Superintendent, The Missionary Medical College Hospital, Vellore, North Arcot District, Madras.

Kaisar-i-Hind Medal (Second Class)

Miss Minnie Rodha Barlow, Assistant Surgeon, Women's Medical Service, Lady doctor in charge, Municipal Zenana Hospital, Dera Ismail Khan.

Miss Hellen Gregory, Superintendent of the Baptist Mission Zenana Hospital, Berhampore, Orissa.

Miss Anne Dorothy Lawrence, Matron, Jadavpur Tuberculosis Hospital, Bengal.

Miss Norah Aileen Williams, Matron, Ranchi European Mental Hospital, Bihar.

S. C. Dutta, Esq., Medical Practitioner, Bengal.

G. P. Phadke, Esq., Medical Officer of Health, Pandharpur Municipality, Bombay.

Kaisar-i-Hind Medal (Third Class)

Miss Gangubai Hadkar, Medical Practitioner, Broach, Bombay.

A. Majed, Esq., Bengal Medical Service, Superintendent, Bengal Vaccine Institute, Bengal.

K. K. Dutt, Esq., attached to the Purulia Leper Home and Hospital, Bihar.

G. G. Raikar, Esq., Private Medical Practitioner, Kalyan, Thana District, Bombay.

Sub-Assistant Surgeon Jemadar R. S. Shaker, I.M.D.

V. K. Waradkar, Esq., Private Medical Practitioner, Katta (Pendur), Taluka Malvan, Ratnagiri District, Bombay.

Rai Bahadur

Mr. B. B. Hazra, Civil Surgeon, Rangpur, Bengal.

Mr. K. B. Sen Roy, Civil Surgeon, Gonda, U. P.

Lala M. R. Sawhney, Clinical Assistant to the Professor of Ophthalmology, King Edward Medical College, Lahore.

Rai Sahib A. N. Sarkar, Lecturer in Midwifery, Patna Medical College, Bihar.

Mr. G. C. Bhaduri, Civil Surgeon (Officiating), Champaran, Bihar.

Mr. N. Chatterji, Assistant Director of Veterinary Services, Orissa.

Rao Bahadur

Major M. R. G. Mudaliyar, Civil Surgeon (retired), Madras.

Vaidyaratna

Pandit C. Misra, Chikitsaka Chaudamani, Ratnamala, Champaran, Bihar.

Khan Sahib

Mr. B. Hason, Medical Officer in charge of Feni Hospital, Bengal.

Dr. K. S. Shah, Superintendent, Punjab Vaccine Institute, Lahore.

Rai Sahib

Mr. N. L. Varma, Medical Officer in charge, Manohar Das Eye Hospital, Allahabad, U. P.

Pandit M. D. Tewari, Assistant Medical Officer of Health, Garhwal, U. P.

Mr. U. M. Gupta, Lecturer in Pathology, Patna Medical College, Bihar.

Mr. M. Das, Sub-Assistant Surgeon, Kanke Dispensary, Ranchi, Bihar.

a small movement of the head is required to raise the lower end of the face tent 10 cm. off the chest. Such a movement may result in very inefficient oxygen administration, especially with draughts such as are liable to occur around the bed of a patient with pneumonia. It is true that the patient might be told to keep his chin down, or that sufficient pillows could be inserted under his head to ensure the correct position, but how many patients with pneumonia or acute heart failure will keep their heads in one prescribed position? Furthermore, lateral movement of the head must also be limited to some extent. It might be thought that by lengthening the front of the face tent its efficiency would be increased. This may well be so, but it should be remembered that any such change will result in further limitation of movement. The only conclusion that can be drawn from these observations is that, with a restless patient, the efficiency of this method of giving oxygen will vary with the position of the patient's head. These remarks apply to the face tent in its present form.

Comfort.—The face tent is light and fairly comfortable. If the chin is kept down a slight sensation of 'stiffness' may be experienced, but we have never found this to be really objectionable.

Ease of operation.—If no effort is made to keep the patient's head in the correct position, the face tent requires little or no attention.

Economy.—At the recommended rate of flow of 6 litres a minute the cost is approximately 6d. per hour.

Co-operation.—The only co-operation from the patient that is required is that he should keep his head in the desired position. In our experience this is often too much to ask of a restless patient.

(2) *The wire frame face tent* (with walls of celluloid).—This presents no advantage over the celluloid face tent described above. It is not so comfortable and not quite so efficient.

(3) *The cardboard face tent.*—This was made by ourselves according to the instructions given by Argyll Campbell. Our workmanship must have been poor as it was found to be less comfortable and less efficient than the wire frame face tent.

(4) *The face tent with curtain.*—We have used a 4½-inch curtain attached to the wire frame face tent (with celluloid walls) exactly as described by Argyll Campbell. This curtain certainly increases the efficiency of the face tent. Furthermore there is no serious wastage of oxygen when the patient raises his head. (At a rate of flow of 6 litres per minute, the percentage of oxygen in the lungs of C. E. G. fell from 60 to 44 on tilting the head backwards.) The main drawback to the curtain is that even normal healthy individuals may find it very uncomfortable after an hour or two. With a rate of oxygen flow of 6 litres per minute we have found that after 5 minutes the air within the box contained 2.4 per cent of CO₂ and that its temperature had risen from 21.5°C. to 27°C. After 15 minutes the temperature had risen to 28.5°C. and the subject was conscious of both the CO₂ stimulus to respiration and of stuffiness of the air breathed. To prevent over-heating Argyll Campbell has suggested that the frame be covered with linen and soaked with water. We have tried this, with discouraging results. Moistening the tent does delay over-heating but after it has been worn for 15 minutes there is little diminution in temperature. This procedure may also add to discomfort by wetting the face. With patients our experience has been the same. The face tent with a curtain will seldom be tolerated for any length of time.

Summary.—The four types of face tent that have been investigated all present certain disadvantages. The efficiency of the celluloid face tent depends partly on the position of the head. A slight tilt of the head backwards may so reduce its efficiency that the patient receives a supply of oxygen which may be inadequate. This type of face tent is therefore only suitable for those patients who will co-operate sufficiently to keep

their heads in one prescribed position. With a curtain properly attached to the face tent these drawbacks are prevented, but the complication of discomfort is added.

THE NASAL MASK

The nasal mask, with its bag attachment, is fully described later. It is as efficient as the face tent with a curtain, but not quite so efficient as the Haldane mask. The alveolar oxygen can be maintained at 45 per cent with a flow of 3 to 4 litres a minute. In our opinion it is the most comfortable of all efficient methods of giving oxygen with the possible exception of the oxygen tent. The mouth and eyes are not confined and the patient can attend to his nose by lifting the mask; expectoration is not interfered with. It is inexpensive to buy and inexpensive to run. With oxygen flowing at 4 litres a minute the cost is approximately 4d. per hour. The only co-operation required from the patient is that he should not displace the mask, and this seldom occurs except in delirious patients. Should this complication arise it at once becomes apparent as the bag attachment no longer rises and falls with respiration.

Summary.—The nasal mask is an efficient, economical, and comfortable method for the administration of oxygen.

THE NASAL CATHETER

The nasal catheter has attained considerable popularity in oxygen administration. A No. 9 catheter is usually recommended and it should be inserted about 3 inches so that the tip lies in the nasopharynx.

Efficiency.—A flow of about 6 litres per minute is required to maintain 45 per cent of oxygen in the lungs.

Comfort.—There are patients with dyspnoea who do not object to a catheter in the nose but there are many who do. Much greater than the mechanical discomfort is the irritation of the mucous membrane where oxygen escapes from the catheter. Even if several holes are cut few patients fail to complain of discomfort if a flow of 6 litres a minute is maintained for more than an hour or two. With the flow distributed through two nasal catheters, sufficient oxygen to raise the percentage in the lung to 45 will seldom be tolerated. The generalization can be made that the nasal catheter, whether single or double, is usually only comfortable when insufficient oxygen is being given. This may not hold in the case of children in whom a flow of ½ litre per minute may be sufficient. At this rate of flow the catheter will probably be comfortable.

Ease of operation.—Once inserted the nasal catheter gives no trouble unless the patient refuses to tolerate it. Insertion of the catheter may not be so simple. In sensitive patients cocaine may have to be used. Insufflation of the stomach with oxygen has been described. With the catheter inserted too far the patient may swallow oxygen with the saliva or food, and serious abdominal distension may result.

Economy.—If the patient will tolerate a sufficient rate of flow it costs about 6d. per hour to maintain 45 per cent of oxygen in the alveoli.

Co-operation.—No co-operation is required from the patient except that he tolerate the method.

Summary.—The administration of oxygen by means of a nasal catheter seems a reasonable and simple procedure. Its simplicity is perhaps its main danger. If sufficient oxygen for an adult is given the catheter may not be tolerated, and it is so easy to reduce the rate of oxygen flow until the patient is comfortable. Under these circumstances the physician is merely deceiving himself if he believes that oxygen is being properly given.

THE NASAL TUBE

With a tube lying just inside the nostril oxygen can very easily be introduced into the respiratory tract. Numerous types have been devised, using either

one or both nostrils; the only essential difference is the method by which the tubes are held in position.

Efficiency.—The efficiency of the double or forked nasal tube is almost identical with that of the nasal catheter. Some workers have found the nasal tube to be somewhat better than the catheter, although it is difficult to understand how this can be so.

Comfort.—We have made extensive use of nasal tubes on all types of patients and have found that few complain of discomfort. If the rate of flow is more than 4 litres a minute the patient may complain of irritation of the nose.

Ease of operation.—If the tube remains in position no difficulty arises, but we have found it impossible to keep the tube in position for any length of time, except with the most co-operative of patients. One would have thought that a small piece of tubing would be easily retained within the nostril, but the slight irritation due to its presence tempts the patient to rub his nose. No matter how the tube is secured most patients will displace it. After a prolonged trial with many different methods the routine use of the nasal tube was abandoned for this reason.

Economy.—The nasal tube is quite economical and to raise the alveolar oxygen to 45 per cent costs about 6d. per hour.

Co-operation.—The only co-operation that is required is that the tube should be left alone. As has already been explained, this is too much to ask of most patients.

Summary.—The nasal tube is an ideal method of giving oxygen, except for the difficulty of keeping the tube in position. We know of no means whereby this technical difficulty can be overcome.

THE FUNNEL

The administration of oxygen by means of a glass filter funnel placed near the mouth is a time-honoured procedure, but it has been shown repeatedly that very little, if any, of the oxygen given ever reaches the lungs. If pressed tightly against the face the funnel may be more effective, but no patient will tolerate this procedure for as much as an hour.

CONCLUSIONS

(1) The indiscriminate administration of oxygen to any patient who is cyanosed and acutely ill is in part responsible for the conflicting evidence on the value of oxygen therapy. Oxygen should only be given when there is a reasonable expectation of relieving anoxæmia. Where cyanosis is due to localized consolidation or to localized collapse of the lung, it can seldom be relieved by oxygen. Where cyanosis is due to a generalized impairment of aeration or to an inflammatory process scattered throughout the lung, oxygen, if properly given, should relieve cyanosis.

(2) An adequate supply of oxygen is as important as the method used for its administration. This can be assured only by the use of a proper flowmeter. A pressure-reducing valve is also recommended.

(3) The most satisfactory methods for the administration of oxygen are the nasal catheter, the nasal mask, and the oxygen tent.

(a) The nasal catheter is often too uncomfortable for continuous use if oxygen is given in amounts adequate for an adult. In infants the catheter may be satisfactory.

(b) The nasal mask is efficient, comfortable, and inexpensive. It is usually easy to operate but occasionally difficulty is experienced in fitting the mask to the nose.

(c) The oxygen tent is comfortable and efficient. It is expensive to buy and to operate and requires more or less expert supervision.

(d) Only four types of face tent were given a trial, and recent modifications of this method may prove to be satisfactory.

An analysis of the hæmatological findings in 57 cases of anæmia in pregnant tea-garden coolie women, with special reference to the results of treatment

By L. E. NAPIER

and

D. N. MAZUMDAR

(Abstracted from the *Indian Journal of Medical Research*, Vol. XXVI, October 1938, p. 541)

AN examination of the blood of 25 males and 25 females showed a low standard of hæmoglobin amongst the so-called normal coolies in the population from which the cases are taken. The mean corpuscular hæmoglobin is also below normal. This is the common characteristic of coolie populations; the significance is discussed.

The cases investigated were provisionally divided into three groups as follows:—

A. *Hypochromic.*—There are in this group 26 cases: of these 7 are microcytic, 18 are normocytic and 1 macrocytic; of these 26 cases, (1) 16 (6 microcytic, 9 normocytic, 1 macrocytic) only received iron and responded to the treatment in varying degrees, (2) 5 (1 microcytic) had iron only and did not respond, (3) 4 had mixed treatment (all normocytic) and responded to treatment in varying degrees, and (4) 1 (normocytic) had mixed treatment and died.

B. *Orthochromic.*—This group consisted of 28 cases, (1) of these 18 (4 macrocytic and 14 normocytic) responded to treatment in varying degrees, (2) 7 died (6 normocytic and 1 macrocytic), and (3) 2 (both normocytic) did not respond to mixed treatment, and 1 received no treatment.

C. *Hyperchromic.*—The three hyperchromic cases were all macrocytic, and all responded to treatment with liver extract.

The response to treatment in these cases is discussed in detail and in 34 cases this is demonstrated by graphs. According to their response to treatment the cases are arranged into two groups, the iron-responding group and the marmite-liver-responding group which correspond very closely to the hypochromic group, and the orthochromic and hyperchromic groups, respectively. Certain ætiological, clinical and hæmatological features in the two groups are contrasted, and the special characteristics of each group summarized.

The ætiological factors in these two types of anæmia are discussed, and the important findings in a dietary survey that was carried out in conjunction with this enquiry are given. The following conclusions were arrived at:—

The population of pregnant tea-garden coolie women as a whole has a low level of hæmoglobin associated with a small pale red blood cell: conditioned iron deficiency, brought about by continuous blood loss from hookworm infection in the presence of a low iron intake, will account for this in part, but not, we believe, altogether, and we consider it possible that a low calcium and/or a low vitamin-C intake may be associated factors.

The anæmia amongst pregnant women can be divided into two groups, characteristically microcytic hypochromic and macrocytic hyperchromic, respectively; the former is an exaggeration of the anæmia in the normal population brought about by the extra demands of pregnancy, but the factors concerned in the latter are not quite so evident, though the response to treatment suggests—and a dietary survey does not negative the suggestion—that there is a relative deficiency in important food factors probably associated with the vitamin-B₂ complex, and other observations indicate that this deficiency is conditioned by the presence of the foetus with its extra demands for substances essential for hæmopoiesis (or less probably its toxic influence) and/or by a state of chronic malaria.

Whilst characteristic examples of each type of anæmia are seen, they seldom occur in 'pure' state and in the vast majority of cases deficiencies of both groups are evident and require rectifying.

"Typhoid Mary"

(From the *Lancet*, Vol. II, 19th November, 1938, p. 1188)

THE death is reported from New York of Miss Mary Mallon, a chronic typhoid carrier, famous as 'Typhoid Mary'. She reached the age of 70, living in a country cottage purchased for her by the State in 1923, and died from a paralytic seizure.

Suspicion that Miss Mallon was a carrier were aroused in 1904 when four fellow servants in the house where she was employed as a cook contracted typhoid fever. These suspicions were confirmed in 1907, when two members of another household for which she worked developed typhoid, one of the cases ending fatally. Actually outbreaks of typhoid fever occurring at varying periods after Miss Mallon's engagement as a cook are traceable as far back as 1900, and even then, as Ledingham and Arkwright have observed, the list compiled by C. A. Soper is probably not complete. It is noteworthy that Miss Mallon had been in her first place for three years before cases began to appear in the household. Subsequent household outbreaks in her employer's family or staff were traced in 1901, 1902, 1904, 1906 (twice), culminating in the 1907

incident, which resulted in Miss Mallon's forcible removal and isolation as a carrier for a number of years. It seems, however, that in 1914 she became a cook in a sanatorium and was again the source of an epidemic. After this she was isolated for nearly ten years, and then housed at the expense of the State. Miss Mallon was a faecal, probably a biliary carrier. Typhoid bacilli, so far as is known, were never isolated from her urine. According to C. H. Browning and his collaborators probably 2 to 5 per cent of all cases of typhoid fever become permanent carriers and in all countries where the disease is still comparatively common, as in the United States of America, they may constitute 0.1 per cent or more of the total population. They are, of course, a constant source of danger to the community in which they live, especially when engaged in the handling of milk or other foodstuffs. In England and Wales medical officers of health have no power to do more than forbid carriers to engage in trades which involve the handling of foodstuffs, but it is clearly of the utmost importance to detect and whenever possible segregate enteric carriers while measures are adopted for their treatment. According to Browning most of those who excrete enteric bacilli for as long as six months after the acute attack will continue to do so, and those who still excrete them after a year will not be cured spontaneously and are to be regarded as permanent carriers. The successful treatment of the chronic carrier, whether biliary or urinary, has hitherto been surgical. So far drugs, vaccines, and physical therapy have proved unavailing. It remains to be seen whether the sulphanilamide group of drugs affect this distressing condition.

Reviews

THE BRITISH ENCYCLOPÆDIA OF MEDICAL PRACTICE.—Under the General Editorship of Sir Humphry Rolleston, Bt., G.C.V.O., K.C.B., D.Sc., D.C.L., LL.D. 1938. Butterworth and Company, Limited, London. (To be completed in 12 volumes.) Sold in complete sets only. Cash price, Rs. 25 per volume. Also available on the instalment system at Rs. 10 per month. Price, Rs. 26-8 per volume. Only available from Messrs. Butterworth and Company (India), Limited, Calcutta. Volume VII. Pp. xxvii plus 718 plus 41

THIS volume includes subjects from hyperchlorhydria to leucorrhœa. It would seem that the original estimate of eleven volumes was optimistic, as at volume VII we are not half-way through the alphabet.* This volume is by far the fattest so far issued, but the actual number of pages is not far above the average. There are an unusually large number of plates.

The first chapter is by Professor Henry Moore of Dublin. The subject is discussed fully. There are some useful sample gastric analyses showing the curves in different conditions. There is also a chart by Ryle and Bennett that is seldom reproduced in full. It shows the analysis of fractional gastric tests of 100 normal persons of three degrees of normality. About 50 per cent have a very narrow range, never over 35 c.cm. or under 25 c.cm. during the most active period of acid secretion, that is, from one and a half to two and a half hours; for 80 per cent of cases the range is slightly wider; but if 100 per cent of normals are to be included the range is a very wide one ranging from achlorhydria to a maximum of 100 c.cm.—these latter presumably include people with what Hurst calls 'the hypersthenic gastric diathesis'.

One is reminded of the fact that experimentally dilute mustard oil will produce a gastritis in some experimental animals. Workers on epidemic dropsy should remember this.

The chapter on impetigo by Dr. L. Forman of Guy's Hospital is a very practical and useful contribution to a subject that enters the daily routine of most practitioners in nearly every country in the world. Mr. Kenneth Walker has written the chapter on impotence. This is a subject that assumes considerable importance in this country and his teaching is certainly applicable here. The ætiology of this condition is very complex and there is in a great majority of cases a strong psychological element. That nervous inhibitions can sometimes be overcome by a small dose of alcohol is no doubt very true, but the practical suggestion that the nervous bridegroom should take a glass of beer before retiring to the nuptial chamber, if followed, might lead to a transfer of the inhibitions to a fastidious bride.

A chapter on insomnia might so easily develop into a glossary of proprietary hypnotics, but Dr. Purdon Martin's contribution is not of this kind. A few hypnotics are named, but the subject has been dealt with in a much higher plane and it is a chapter that will be found very useful to the practitioner.

Intestinal obstruction is a subject of primary importance to both physician and surgeon. This chapter, contributed by Mr. N. L. Eckhoff of Guy's Hospital, is a well-balanced discussion, with of course numerous cross-references to other chapters where the various causes of acute and chronic obstruction are dealt with in greater detail.

The conduct of labour naturally calls for a textbook rather than a chapter: this has for all practical purposes been provided in the 177 pages, divided into 15 chapters, devoted to this subject. There are ten contributors to these chapters; they include Lieut.-Colonel Green-Armytage, who appropriately has written on labour in the tropics.

*Since this review was sent to press the publishers have announced that the work will be completed in 12 volumes.

Again tropical diseases have been well served. The chapter on leprosy is written by Dr. E. Muir; this ensures a masterly and practical treatment of this important disease. Kala-azar has been generously treated, being allowed 36 pages and a coloured plate. There is another chapter in this volume on cutaneous leishmaniasis in which a classification of the leishmaniasis is given: both these are written by Dr. L. Everard Napier. There is a good chapter on lathyrism by Colonel R. N. Chopra. There are thus in this volume, five chapters that are of special interest to workers in the tropics (and, incidentally, four have been contributed by present or past members of the staff of the Calcutta School of Tropical Medicine).

The same high standard set by the earlier volumes is maintained throughout this volume.

LEUKÆMIA AND ALLIED DISORDERS.—By C. E. Forkner, A.M., M.D. 1938. The Macmillan Company, New York (60, Fifth Avenue). Pp. xvii plus 333. Illustrated. Price, \$5.00

LEUKÆMIA is a common disease in this country. How common, it is difficult to say. In western countries, England for example, a large spleen attracts the immediate attention of the medical examiner and, if the enlargement is considerable, 'leukæmia' will immediately arise in his mind. In India, this is not so: he will first think of malaria, then kala-azar, and possibly he may subject the patient to a variety of treatments before their ill success makes him investigate the case more carefully.

This is unfortunate. The importance of making a diagnosis of leukæmia is far from academic. It is a very great 'negative' importance, as it will save the patient from many months of futile treatment. But it is more than this. Leukæmia can, one supposes, strictly be classed as an incurable disease, but to prolong life is perhaps more important and one can certainly do this in chronic leukæmia. Further, one can bring the patient back to a moderate state of health for this period of prolonged life.

The average textbook of medicine deals with leukæmia unsatisfactorily from a practical point of view and even chapters in books on blood diseases and in encyclopædias tend to be disappointing.

It is therefore with some feeling that we welcome this important book on an important subject. The book is a very careful review of the available literature on leukæmia by one who has made a special study of the disease over a number of years and has had first-hand experience in at least two countries, China and the United States of America. It is a critical review but the author does not force his own opinion, and his summings-up are fair and convincing.

It is unnecessary to describe the book beyond saying that it is a model monograph. Of its three hundred odd pages, over sixty are devoted to the bibliography which must be the most complete one on the subject in existence. There are a few useful coloured and other plates. Also a number of charts and text-figures.

The reviewer read the chapter on that comparatively new disease, but only new because it was not previously recognized, monocytic leukæmia, with particular interest. In it the author condemns the names 'reticulosis' and 'reticulo-endotheliosis' as applied to this disease, in no uncertain terms. His own table, quoted from another publication, differentiating the acute leukæmias will be found a valuable guide to hæmatologists (Why is this and every other table referred to as a 'figure'? And, incidentally, it is not on p. 278, as is stated when it is later referred to. A few mistakes like this suggest that the proof-reading was not done with the meticulous care that would have been appropriate to the author's high standard).

We can very strongly recommend this excellent monograph to teaching physicians, hæmatologists, and all others who are interested in this disease which is a very important one in this country.

L. E. N.

THE NEW INTERNATIONAL CLINICS.—Edited by G. M. Piersol, M.D. Volume II. New Series One (Old 48th). 1938. J. B. Lippincott Company, Philadelphia and London. Pp. xxx plus 315. Illustrated. Price, 50s. for 4 volumes. Issued quarterly. Obtainable from Messrs. Butterworth and Company (India), Limited, Calcutta

THERE are a number of important and interesting articles in this volume of the *International Clinics*, but perhaps the most practically useful one is on sacro-iliac joint pain. This is a long chapter and is divided into three sections, the first on the finer anatomy of the joint, the second on its mechanics, and the third on the ætiology, diagnosis and treatment of pathological conditions of this joint. The treatment consists in manipulation, and not only is the case for this form of treatment well made out, but very explicit details for the procedures are given. Lower back pain is a very troublesome and obstinate condition and, if organic bowel and prostatic disorders are excluded, the sacro-iliac joint disease is probably the most common cause; it is therefore important to know how this condition may be cured.

Another interesting chapter is anthracotherapy, or the intravenous injection of carbon particles. The immediate reaction to casual perusal of this chapter is that of reading a quack advertisement, but one soon changes one's mind. The obvious sincerity of the writer has made the reviewer decide to give this treatment an early trial. It is not a panacea, but acts in such divergent conditions as herpes zoster, gangrenous appendicitis, articular rheumatism, acute gonorrhœa, lymphangitis, and furunculosis.

The article on lymphogranuloma venereum is distinguished by having a bibliography of 138 references; this alone establishes its value, though the references are not all directly referable to this disease.

Another useful bibliography will be found in Dr. Claude Forkner's chapter on the relationship of leukæmia and pregnancy, a very painstaking study.

Other practical and useful chapters are on mandelic acid treatment of urinary infections and on insulin shock treatment of schizophrenia.

SYMPTOMS AND SIGNS IN CLINICAL MEDICINE: AN INTRODUCTION TO MEDICAL DIAGNOSIS.

By E. N. Chamberlain, M.D., M.Sc., F.R.C.P. With a Chapter on the Examination of Sick Children.—By N. B. Capon, M.D., F.R.C.P. Second Edition. 1938. John Wright and Sons, Limited, Bristol. Pp. xi plus 435. Illustrated. Price, 25s.

Two issues of the first edition in the course of a year and a half and a second edition a year later, proves definitely the popularity and usefulness of this book.

The author has set forth in this volume what a medical student must learn when he enters the medical wards, viz, the method of obtaining a correct and relevant history of illness of the patients, the technique of physical examination and of eliciting physical signs; so that he may learn how to solve the problem of diagnosis. The author has dealt with these subjects in an attractive and interesting manner. The description of the methods of examination of the patient and of eliciting the various physical signs—usually accompanied by photographs or diagrams—cannot but impress the student. The short descriptions of the common diseases of the different systems have been included and will be of help to the students in diagnosis of the cases.

The descriptions of the various procedures in medical case-taking are adequate in most instances. A few of the sections, e.g., those dealing with the types of gait or speech in different nervous diseases, should have been more elaborate and the different features of the various types described in more detail.

The section of hæmatology should be brought more up to date. The classification of anæmias is unsatisfactory. The cells labelled as megaloblasts in the colour plate, showing normal and primitive red

blood cells, is an early normoblast. A description of the modern absolute standards of the red cells, viz, mean corpuscular volume, mean corpuscular hæmoglobin, and mean corpuscular hæmoglobin concentration, would have been much more useful than that of the method of determining the colour index as given, which is of doubtful value in determining the presence of hyper-, ortho- or hypochromia. The section dealing with clinical pathology and biochemistry should contain more details about some of the tests than mere mention by name, e.g., urea-clearance test, sedimentation rate of blood. Inclusion of colour plates showing malarial parasites and the common helminthic ova and protozoal cysts would be useful for students and practitioners in the tropics.

The printing and get-up of the book and the illustrations are excellent. The book will prove extremely valuable to the senior medical students and general practitioners.

P. C. S. G.

MIDWIFERY.—By Ten Teachers. Under the Direction of Clifford White, M.D., B.S. (Lond.), F.R.C.P. (Lond.), F.R.C.S. (Eng.), F.C.O.G. Edited by Sir C. Berkeley, C. White and Frank Cook. Sixth Edition. 1938. Edward Arnold and Company, London. Pp. xii plus 676. Illustrated. Price, 18s.

THIS widely-used textbook has, in its new edition, not only maintained its previous high standard but has in several particulars improved on it. Some of the earlier editions have to a certain extent been marred by excessive conservatism in dealing with recent advances. This feature has completely disappeared from the latest edition. Every section of the book is completely up to date. Written primarily for the student going up for his final examinations, this book will also appeal widely to the busy general practitioner because no words are wasted anywhere. He will also consult the book with complete confidence because the blending of the ideas of the ten well-known teachers precludes the possibility of being misled by any personal fads or prejudices.

Readers in India and other English-speaking tropical and subtropical countries will be disappointed that there is no reference to tropical diseases in pregnancy. The absence of such a section limits the usefulness of the book to a certain extent. There are teachers in London who could do justice to an appendix on this subject.

Apart from this there is little in the way of criticism to make, but the following few points are perhaps worthy of mention:—

In the treatment of vesicular mole, no advice is given for those difficult cases where the os is closed or nearly closed.

Mandelic acid is recommended in cases of pyelitis of pregnancy, but no reference is made to the fact that this substance causes great indigestion in pregnant women and in the reviewer's opinion is unsuitable.

In the section on mechanism of labour the authors make no mention that the head usually engages in the transverse diameter.

One feels too that undue stress is laid on the active removal of the remains of the ovum in incomplete abortion. It would have been worth mentioning that in a large proportion of cases good results may be obtained by expectant treatment consisting of injections of pitocin, etc., especially where surroundings are unsuitable for active treatment or other contra-indications exist.

However, such unimportant criticisms are but an indirect compliment and the authors are to be congratulated on the production of such an outstanding edition of what has become one of the leading textbooks on obstetrics.

G. P. C.

CLINICAL OBSTETRICS.—By A. L. Mudaliar, B.A., M.D., F.C.O.G. 1938. Oliver and Boyd, Edinburgh (Tweeddale Court). Pp. xi plus 819, with 204 text illustrations and 9 in colour. Price, 27s.

His present and past students all over India will welcome the written version of Professor Mudaliar's teaching, and they will not be disappointed. The book covers the whole field of obstetrics in a clear and concise manner. The special problems which are encountered in the tropics receive adequate attention, a thing not usually found in textbooks written primarily for readers in Great Britain and America. For this reason the book should prove popular with all practitioners of obstetrics in the tropics. The author does not hesitate to give his own personal opinion where relevant, and this tends to make the book more readable and interesting.

There are, however, several criticisms which one feels should be made. The chapters on contracted pelvis are arranged in a very confusing manner. One wonders if it is not a printer's error that the rather brief reference to Caldwell and Moloy's classification appears at the end of the chapter on 'Management of Labour in Contracted Pelvis' instead of being included in the chapter on 'Contracted Pelvis' in which the older classifications appear. This section is also marred by the surprising omission of any adequate mention of x-ray pelvimetry. Although x-ray pelvimetry is practised in all big centres giving very accurate results and a description is included in practically all modern textbooks of midwifery, yet this statement appears, 'Much work remains to be done to enable us to judge with any accuracy by radiograph alone the extent of contraction in flat and generally contracted pelvis'.

Nor can the section on 'Physiology of the Female Generative Organs' be called up to date. It contains no reference to the hormones of the ovary and pituitary. No practitioner can face the medically educated public of to-day without a complete knowledge of hormone therapy. The sketchy appendix which is devoted to this subject will not satisfy even the most uncritical. The importance of progesterone therapy in habitual and threatened abortion receives only the barest mention in this appendix, and this treatment is not mentioned at all in the relevant chapters. The units employed are not given, nor the doses.

The chapter on hookworm infestation during pregnancy is excellent, but the importance of blood transfusion in extreme cases is not stressed. In fact blood transfusions are not mentioned at all in this connection. This serious omission is to some extent atoned for by the appendix on transfusions. Here one would have liked to have seen a sphygmomanometer recommended as an arm-band round the donor's arm, since this detail makes all the difference where transfusion with citrated blood is used. In the description of the direct method using a special syringe, the author advises puncturing the radial artery of the donor. Such a drastic procedure is entirely unnecessary. A vein of the donor would be very much easier to handle, and hæmatomata are less likely to develop.

The statement that in cephalic presentations Roederer's obliquity (excessive flexion) causes distocia is dangerous teaching. Students who take this statement too literally may well be led to false conclusions. Most obstetricians will agree that excessive flexion is a result of distocia and not the cause.

Few will agree with the author when he recommends 5 minims of liquid extract of ergot in cases of threatened abortion.

There is no mention of carbon dioxide therapy in the treatment of asphyxia neonatorum. This is obviously an accidental omission since the reader is advised earlier to keep a cylinder of the gas in readiness.

However, the intention is not to belittle what is really a most excellent textbook in spite of the few

relatively unimportant points mentioned above. It is well bound, well printed and generously illustrated.

G. P. C.

THE ABNORMAL IN OBSTETRICS.—By Sir C. Berkeley, M.A., M.C., M.D. (Cantab.), F.R.C.P. (Lond.), F.R.C.S. (Eng.), M.M.S.A. (Hon.), F.C.O.G., V. Bonney, M.S., M.D., B.Sc. (Lond.), F.R.C.S. (Eng.), F.R.A.C.S. (Hon.), M.R.C.P. (Lond.), and D. MacLeod, M.S., M.B. (Lond.), F.R.C.S. (Eng.), F.R.C.P. (Lond.), M.C.O.G. 1938. Edward Arnold and Company, London. Pp. viii plus 525. Price, 18s.

No obstetrician, whether specialist or general practitioner in whose work midwifery plays an important part, can afford to be without this masterly book in whose 500 pages is packed an immense amount of concisely written information on all subjects with which the obstetrician may be confronted. Much of this information is to be found in no other textbook and has in fact been largely gathered from recent authoritative articles in various medical journals, seasoned with the great personal experience of the authors. The book has the advantage of not being cluttered up with chapters on anatomy, physiology, normal labour, etc., which must necessarily form a major part of any textbook meant for medical students. Neither do the ordinary obstetrical operations, with which all who practice midwifery are familiar, find any place in this book.

There is, however, one chapter which is not in keeping with the general standard of the book, i.e., the chapter on mental diseases written by Sir Hubert Bond. The author has contrived to make what is admittedly a difficult subject still more difficult by the use of very long and complicated sentences and by a wordy and diffuse treatment of his subject. One does not doubt that all the necessary information is present but few will have the patience to read it.

Apart from this it is difficult to single out any chapter for special mention. Readers in India will be pleased to find that tropical diseases are adequately dealt with although perhaps not in quite the same detail as most other subjects. The chapter on injuries and deformities of the newborn is especially thorough and complete.

A useful bibliography is given which will be valuable for those who wish to consult the original works.

G. P. C.

VITAMINS AND VITAMIN DEFICIENCIES.—By L. J. Harris, Ph.D., Sc.D. (Cantab.), D.Sc. (Mano.), F.I.C. Volume I. 1938. J. and A. Churchill, Limited, London. Pp. xiv plus 204, with 50 illustrations. Price, 8s. 6d.

This is the first volume of an important new series of books on the vitamins. This series is described as 'a comprehensive but concise review of modern knowledge about vitamins'. The first volume appears to justify this description.

The writer in his preface refers to the saying that there are two ways of learning a subject, one to read every book available and the other to write a book oneself. He prefers the second way, and the reviewer agrees with him. One's thoughts are liable to be loose, but to put them on to paper they must be pulled together and arranged; this is the only way to obtain a sure foundation from which to take the next step.

The trouble is that when anyone writes a book they always want to publish it: this is quite unnecessary and, as a general rule, the practice is to be deplored. We can, however, allow exceptions to this general rule and Dr. Leslie Harris has an undeniable claim to be included amongst these exceptions.

The first chapter is historical; it is one of the most difficult problems to do justice in the matter of assigning rights of priority to medical discoveries of the present day. The subject is best left to the

long-distance historian: not that we really believe that he gets a better view, but by that time nobody really cares and so no feelings are hurt. You can pick Gowland Hopkins, Funk, Holst, Grigns, Eijkman, or go back to Lind and Captain Cook, if you like, as the discoverer of vitamins. The author has given a very fair and open summary of the early history of our knowledge on vitamins.

The main subject of this volume is, however, vitamin B, the anti-beri-beri vitamin. The gross avitaminosis and the various degrees of hypovitaminosis, clinical, sub-clinical and problematic, are discussed. The incidence in different foodstuffs, the standard requirements, and the biological and clinical tests for this vitamin are reviewed and the important ones described in detail.

By way of concluding this review we will quote from the foreword by Sir Frederick Gowland Hopkins:

'In the present volume Dr. Harris has, I feel, attained to remarkable success in overcoming the difficulties inherent in his task. He is deeply versed in the literature of the subject and his own ample experience of personal research in its service fits him for a proper appraisal of the work of others. The result is a book of exceptional adequacy. Under the head of each known vitamin in turn available knowledge is clearly marshalled, and, so far as I can discover, only the unessential is left out.'

'I can strongly recommend the book to all students who desire acquaintance with the present position and outlook in the field of vitamins, and believe that the specialist will welcome an admirable summary of the facts available to-day and a bibliography fully up to date.'

THE FUNDAMENTALS OF INTERNAL MEDICINE.—By W. M. Yater, A.B., M.D., M.S. (in Med.). 1938. D. Appleton-Century Company, Incorporated, London and New York. Pp. xlv plus 1021. Illustrated. Price, 35s.

The title of this book led the reviewer to anticipate he was going to encounter something different from the usual run of books. In this he was disappointed because it is only an attempt to condense the whole of medicine including dermatology, tropical medicine and dietetics into 1002 pages. The result is little more than a medical dictionary without the advantage of the matter being arranged alphabetically.

The brevity of description may be appreciated if one records that diseases caused by protozoa and metazoa are dealt with in 17 pages in the chapter on infectious diseases, and diseases of the skin are described in 54 pages. Such brevity would perhaps be admissible if the information given were always correct, but one finds in the treatment of kala-azar the newer antimony compounds are dismissed with the sentence 'Even more powerful antimony preparations are stibosan and urea-stibosan'. Such a jumble of meaningless and incorrect names is almost incredible. In treatment of malaria all that is said of plasmodium and atabrin is 'If hæmoglobinuria exists, only small doses of quinine should be given until the urine is clear, but plasmodium and atabrin may be used'. In the treatment of hookworm infection all the drugs are mentioned but there is no warning against their toxicity, even of carbon tetrachloride, and the only treatment mentioned for tapeworm is oleoresin of aspidium.

Other sections such as those on diseases of the respiratory system, of the heart and blood vessels, and of the digestive system are possibly better done, but the reviewer's task is to discuss the book from the point of view of the Indian practitioner, therefore a few of the errors and omissions in treatment of some of the diseases he encounters daily are emphasized, and the final verdict is that this is not a book that can be recommended for students or doctors in tropical countries.

P. A. M.

THE TROUBLED MIND: A STUDY OF NERVOUS AND MENTAL ILLNESSES.—By C. S. Bluemel, M.A., M.D., F.A.C.P., M.R.C.S. (Eng.). 1938. Baillière, Tindall and Cox, London. Pp. ix plus 520. Price, 13s. 6d.

This is the second book, entitled *The Troubled Mind*, that has been published recently. Both books discuss the 'troubles' of the mind from an unorthodox standpoint, but that is nothing in the disfavour of either. Dr. Bluemel's book is remarkable for the huge number of case histories with which he illustrates each mental trouble that he discusses. In fact, there are really too many. The etiology of by far the greater number of the troubles cited is hardly touched on. Too little space is given to treatment, particularly to psychotherapeutic treatment. The index contains no reference to psychotherapy and only to psycho-analysis where the author disparages it. The best chapter in the book is that entitled 'The Public Lunatic'. It deals almost exclusively with modern dictators, reformers, evangelists and miracle workers. Mental hygiene and prophylaxis are not touched on.

A TEXTBOOK OF CLINICAL PATHOLOGY.—Edited by Roy R. Kracke. Baillière, Tindall and Cox, London. Pp. 567, with 31 coloured plates and 205 diagrams in black and white. Price, 27s.

This is a volume which contains the accumulated experiences of a dozen teachers of the different medical schools of the United States of America. The editor is of opinion that it is not possible to write a book single-handed which will be comprehensive of all the laboratory methods and their interpretation. It is for this reason that he has secured the services of experts who are engaged in teaching these subjects to their students for many years. The editor does not want this book to be intended as a guide to the various laboratory methods but as an aid to the interpretation of results and their application to clinical medicine. We fully agree with the author that 'it is far more important for students of medicine to know the significance of achlorhydria than the technique of its determination', particularly in view of the fact that most of the laboratory tests are carried out nowadays by non-medical assistants. In every subject, one standard technique has been elaborately described and fully illustrated, thus lessening the task of the clinical pathologist. Every branch of clinical pathology has been included, viz, the examination of blood, serum, sputum, urine, stool, cerebrospinal fluid and material for virus infections and each one of the subjects has been dealt with in the most practical way. In fact it will not be exaggeration to state that even a beginner will be able to manage his work satisfactorily with the help of this book if he is placed in charge of the clinical laboratory of any modern hospital. The book is full of well-selected diagrams which have been specially chosen to illustrate the crucial points in the various clinical examinations. A short but useful bibliography has been attached at the end of every chapter for the benefit of those who intend to know further details about any subject.

It is difficult to make an unfavourable comment on a book of this nature. The reviewer would, however, be happy if, instead of only 2 pages, more space were given to the preparation of culture media. In some places, brevity has been observed at the cost of clarity and occasionally there has been some diversion to theoretical discussion which would have been better avoided in a textbook of clinical pathology.

This admirable book is recommended to every student, general practitioner, and laboratory worker for constant reference.

M. N. D.

A TEXTBOOK OF PATHOLOGY.—Edited by E. T. Bell, M.D. Third Edition. 1938. Henry Kimpton, London. Pp. 894. Illustrated with 412 engravings and 2 coloured plates. Price, 42s.

With the advancement of medical science as a whole, the scope of pathology is no longer confined to

the study of morbid anatomy and morbid histology alone. In every branch of modern medicine and surgery accurate diagnosis is always the aim which is attained by the thorough understanding of the abnormal physiological conditions prevailing at any particular phase or aspect of the disease.

Professor Bell and his colleagues of the University of Minnesota have very ably succeeded in producing a textbook for medical students which meets the requirements for this basic knowledge. The planning of the chapters is highly commendable in so far as it takes the student through all the aspects of the various diseases—common, uncommon, and rare—and, instead of the stereotyped description of the pathology and morbid histology of a particular diseased condition, one is pleasantly surprised to find the most up-to-date information on subjects like genesis of tumours, virus diseases, blood diseases, neuropathology, etc., dealt with in accordance with the present-day trend of modern and accepted scientific thought.

Pathological physiology is the basis of medicine and the authors may be said to have attained the almost impossible task of putting this highly technical subject in a very lucid and palatable form. Of the 414 illustrations a very large percentage is reproduced from photographs of actual cases and specimens in the collection of the authors and the drawings are mostly original—which gives the book a high scientific status indeed. After a careful study of the volume one cannot but testify to the just claims of the authors that the student will learn to look upon 'clinical medicine as a direct continuation of his pathological studies and not an abrupt entrance into a new field'.

CLINICAL ALLERGY DUE TO FOODS, INHALANTS, CONTACTANTS, FUNGI, BACTERIA AND OTHER CAUSES, MANIFESTATIONS, DIAGNOSIS AND TREATMENT.—By A. H. Rowe, M.S., M.D. 1937. Baillière, Tindall and Cox, London. Pp. 812, including Appendix and Bibliography. Price, 37s. 6d.

This useful volume deals with the nature, mechanism, clinical manifestations, diagnosis and treatment of the allergic conditions at some length. In addition to a consideration of the well-recognized manifestations of allergy such as asthma, hay fever, gastro-intestinal allergy, allergic dermatoses, etc., many conditions which may possibly be allergic in nature have been discussed. Of the latter conditions a very interesting one is allergic toxæmia giving rise to symptoms such as fatigue, exhaustion, lack of energy, depression, etc. Food allergy plays a most important rôle in the production of these toxæmias, although the seasonal toxæmias may be due to pollen or other inhalant allergens. The diagnosis and treatment of these allergic toxæmias is carried out on the same lines as of other allergic manifestations.

The author advocates the use of stock respiratory vaccines in the treatment of patients with asthma, in order to raise their immunity to severe head colds and bronchitis. This raised immunity, according to the author, would benefit the patient in two ways. Firstly, 'the bronchial infection secondary to the asthmatic attacks from some type of allergen are less likely', and secondly, 'with less likelihood to such infection, the allergic balance of a patient which ordinarily may suppress mild food or pollen sensitization is not upset'. It is difficult to understand the use of stock respiratory vaccines for prevention of head colds when the evidence at present available points to these 'colds' being caused by a filterable virus. There is no evidence at all that 'colds' can be caused by any of the members of the respiratory flora and as such there is no *a priori* reason for a vaccine from one or more of these organisms acting as a prophylactic against colds. Extensive clinical trials with these vaccines have failed to show any protective value against colds. The use of stock vaccines for prevention of bronchitis is also difficult to understand when we take into account the enormous numbers of antigenic

types of such members of the respiratory flora as streptococcus and pneumococcus, each antigenic type being immunologically specific.

D.

MALARIA IN THE NETHERLANDS.—By N. H. Swellengrebel and A. de Buck. 1938. Scholten and Holkema Limited, Amsterdam-G., Rokin 74-76. Pp. viii plus 267. Illustrated. Price, DFL. 5

THE authors apologetically present their offspring to god-parents, the world over, but they think that an account of its conception and development in relation to the simple conditions pertaining to the Netherlands must prove instructive elsewhere to malarialogical obstetricians.

They say that in the Netherlands the number of variable factors in the malarial constellation are so few that, for the elucidation of the incidence of the disease, there is presented a field of observation comparable with that of a laboratory experiment, and so they call their book 'a pocket-edition' of malarial epidemiology. One may say at once that the hypothetical pocket bulges with treasure, and if indeed the picture that the authors unfold illustrates a sunnier syndrome than that in other countries, God help these!

The fact is that one is astounded by the intricacy of the matter that has been here so untrivially unravelled. The successive chapters present the facets of the picture; man and not the mosquito serving as host of the parasite during the inter-epidemic season, malaria not to be eradicated but controlled to some extent by drugs, the single human habitation the focus of the epidemic, and so on and so forth, one canvas after the other portraying an exemplary analysis of the experimental field and of their field experience.

One should not here go into any further detail but nevertheless reference will be made to one point. It will be remembered that Ronald Ross pointed out that the incidence of malaria in a community was not correlated with the number of gametocyte carriers, that the only factor determining the issue was the number of anophelines. He specifically stated 'whether everyone or only one person is infected to start with the ultimate result will be the same'. His teaching, one would have thought, would have attracted some notice, but has been disregarded by writer after writer even by those considered to be authorities: these have sought to give such a factor as the immigration of gametocyte carriers an important place in the epidemiology of the disease and have even based malaria control entirely upon this doctrine. It is therefore of interest to read in this book (page 250) of infection being imported by immigrants but terminated by its failure to keep anopheline infection going; the interest of the matter being that there is something in conformity with Ross' thesis.

These successive chapters amply justify the object of the essay and it is not too much to say that it is a picture of the most brilliant piece of epidemiological work that has ever been accomplished.

It is a lesson indeed to those parochial-minded scientists in India who have been heard to maintain that 'surveys' are so little science that they can be given over derogatorily to the provinces to support, little appreciating that Nature is an open book for those who will to read and in so far as they are fitted to understand, and forgetting the arch-surveyor Darwin for these let the laboratory method provide their only pride, whereas let the contemned be proud of a profession that can nurture the begetters of such a picture as this.

C. S.

THE SEASONAL PERIODICITY OF MALARIA AND THE MECHANISM OF THE EPIDEMIC WAVE.—By C. A. Gill, M.R.C.P. (Lond.), M.R.C.S. (Eng.), D.P.H., D.T.M. & H. (Eng.), Colonel, I.M.S. (Retd.). 1938. J. and A. Churchill Limited, London. Pp. xi plus 136. Illustrated. Price, 10s. 6d.

WE admit that malaria is a seasonal disease and that its periodicity varies with climate and country, but

we cannot always account for the underlying causes, apart from the fact that life-habits of mosquitoes may play a part. Again, when we attempt to explain the sudden epidemic waves we find ourselves all the more lost.

Dr. Gill has reviewed all the available literature from different countries to bring fresh light on the problem and put forward a provisional explanation based on what he calls the relapse factor. He has given an instructive analysis of the European types of seasonal prevalence; the features of the North Indian type of epidemic and the Ceylon epidemic have also been dealt with.

The book is full of facts, and every malmiologist should go through it.

R. C.

ARTHRITIS, FIBROSITIS AND GOUT: A HANDBOOK FOR THE GENERAL PRACTITIONER.—By C. W. Buckley, M.D. (Lond.), F.R.C.P. (Lond.). 1938. H. K. Lewis and Company, Limited, London. Pp. viii plus 153, with 14 plates containing 24 figures. Price, 7s. 6d.

THE literature on rheumatic diseases is enormous; yet the whole subject seems to be shrouded in a fog, while treatment furnishes the most lucrative field for quackery of every kind. The differentiation and nomenclature of the conditions commonly grouped together under the designation 'rheumatic' still furnishes the ground for differences of opinion which only bewilder a general practitioner.

Dr. Buckley should be congratulated for bringing out this little book which is very complete, practical and readable. It dispenses with the historical and controversial matter as far as possible, and gives a clear and concise picture of the various disabling conditions of articular origin with reference to aetiology, pathology, clinical picture, diagnosis and treatment.

After an introductory chapter the book deals with rheumatoid arthritis, chronic villous arthritis, osteoarthritis, spondylitis, fibrositis and gout. The modern therapeutic measures have been fairly discussed. There are radiological plates illustrative of various conditions, and a short bibliography has been included at the end of the book.

The book can be thoroughly recommended to the general practitioners for the management of the unfortunate sufferers.

R. C.

CLINICAL ROENTGENOLOGY OF THE DIGESTIVE TRACT.—By M. Feldman, M.D. 1938. Baillière, Tindall and Cox, London. Pp. xvi plus 1014. Illustrated. Price, 45s.

THIS is in many ways an epoch-marking work on diseases of the alimentary tract. It covers the whole tract from the oesophagus to the rectum, and embraces every aspect of the subject including clinical, surgical, and pathological points of view. In other words, it gives a complete summary, culled from the author's experience and study of all important writings on the subject, of our present knowledge of the radiological aspects of gastro-intestinal diseases.

The style is lucid, reproduction of skiagrams excellent, and arrangement of subjects logical. There are sections on the gall bladder and pancreas which after all are offshoots of the intestinal canal.

In addition, under the heading *Miscellaneous* are grouped the radio diagnostic aspects of abdominal conditions not directly connected with the digestive tract.

Another distinctive feature is the large number of references at the end of each chapter. These embrace all the important writings on the subject-matter of the chapter; so it forms a complete work of reference not only for the specialist, but also for the general practitioner, on account of the correlation of the radiological picture with clinical and pathological findings.

The material is presented in 220 chapters profusely illustrated with x-ray pictures and drawings all artistically reproduced.

This is a work which should find a place on the shelves of every radiologist, physician and surgeon interested in the diagnosis of diseases of the gastrointestinal tract.

J. A. S.

THE CHEMISTRY OF THE STERIDS.—By Harry Sabotka. 1938. Baillière, Tindall and Cox, London. Pp. xiii plus 634. Illustrated. Price, 38s.

THE book supplies us with a much-needed monograph on sterols and steroids. The author traces the history of their investigation up to the beginning of the nineteenth century and from that time up to the beginning of 1937 he gives references to all relevant literature. There was much confusion as to nomenclature in the older literature and he has given us the new and more rational names along with the older ones. The earlier chapters deal with the traditional methods of structural research, with the newer ones of selenium dehydration, thermic cyclization, etc. The formation of the reaction product has been explained in the light of the accepted cyclopentenophenanthrene structure. There is a chapter on steric considerations. This portion of sterid chemistry is still incomplete but the problems have been discussed in a clear manner and there are some useful suggestions. The chemical and physical properties of bile-acids and choleic acids, which are of great biological interest, have been treated in two chapters and there is a list of choleic acids known up to date. The sterols, hormones, cardiac glycosides, carcinogens, and sapogenins are treated in a separate chapter with short notes and references to original literature. The last chapter deals with the different colour reactions used in biological assays. The synthetic side of sterid chemistry has not, however, been dealt with in this book. There are numerous tables of physical and chemical properties of similar compounds for comparative study and the theoretical chemist will have enough classified data collected and sorted on which to base his theories.

A large bulk of the book, from page 176 to page 496, is devoted to a classified catalogue of all sterids and their derivatives, with their structural formulae, systematic designations, physical constants, occurrence, formation, chemical reactions, transformations, etc., from all sources available up to 1st January, 1937. The bibliography comprises most publications of chemical and biochemical interest on bile acids, sterols, and other sterids which have appeared before 1st January, 1937, and the last few pages are devoted to the graphic formulas of many of these compounds.

The book is the first of its kind to present a connected and comprehensive account of the work done up to date. It will thus be very useful not only to biochemists and advanced research workers but also to all those interested in the biologically active natural products like sex-hormones, antirachitic vitamins, carcinogenic agents, cardiac glycosides, etc., and will form a valuable addition to all scientific libraries.

S. G.

MEDICAL RESEARCH COUNCIL. SPECIAL REPORT SERIES, NO. 231. 'REPORT ON RADIUM BEAM THERAPY RESEARCH, 1934-38'.—By Constance A. P. Wood, L. G. Grimmett, T. A. Green and others, under the Direction of the Governing Body of Radium Beam Therapy Research. Published by His Majesty's Stationery Office, London. 1938. Pp. 77. Illustrated with text-figures and coloured plates. Price, 4s.

'THIS report records the results of four years' research into the treatment of cancer by means of the rays from a large mass of radium situated at a distance from the patient, in contradistinction to the more usual type of radium therapy in which much smaller amounts of radium in suitable containers are inserted by a surgical operation directly into the tissues, or, in the case of superficial tumours, are applied directly

to the skin. The method here described is known as "radium beam therapy", or "telerradium therapy", and it was first developed in France, Belgium, the United States, and more extensively in Sweden'.

'During the first four years of the inquiry, the use of this method of treatment has been restricted to cases of cancer of the mouth, tongue, pharynx and larynx, which are relatively accessible to radium therapy and in which, by reason of the superficial sites of the growths, the local effects of the irradiation may be readily observed. Most of the patients referred to this treatment have been in an advanced and inoperable stage of cancer, and it will be seen from the report that the results have been encouraging. The number of patients so far treated is too small for any statistical comparisons, but it is believed by those well qualified to judge that the results obtained by radium beam therapy compare favourably with those to be expected from surgery. Moreover, these results have been obtained without any mutilation of the patients. On the other hand, it is necessary to mention that the patient with cancer undergoing radium beam therapy cannot expect to escape a period of some discomfort during and immediately after the treatment; such discomfort appears to be almost inevitably associated at present with the exposure of the tissues to massive irradiation'.

'Of even greater importance than the actual therapeutic results so far recorded are the new technical methods which have been elaborated as the result of close co-operation between physicists and clinicians, and which are described in careful detail by the investigators concerned. The procedures used in this research, both for the treatment of patients and for the protection of the staff, should be applicable not only to radium beam therapy in its further evolution; they should be widely adaptable also to the needs and future developments of other types of radiotherapy for cancer'.

This is a valuable report illustrated with a number of figures and some good coloured plates. No one interested in the subject can afford to neglect this authoritative report.

MEDICAL RESEARCH COUNCIL. SPECIAL REPORT SERIES, NO. 232. 'MEDICAL USES OF RADIUM. SUMMARY OF REPORTS FROM RESEARCH CENTRES FOR 1937.' 1938. Published by His Majesty's Stationery Office, London. Pp. 48. Illustrated. Price, 1s.

'THIS report—the sixteenth in a yearly series—summarizes the research done with radium or radium emanation during 1937 at some twenty hospitals or other institutions, most of which hold radium on loan from the Medical Research Council. The main scheme of work is under the general supervision of the Radiology Committee, to whom the Council are indebted for the preparation of these annual summaries'.

'The research described is partly experimental and partly clinical. The experimental section deals with laboratory investigations both of the physical aspects of radiations and of the effects of gamma rays on proteins and living tissues. The clinical sections describe new technical methods used for the radium treatment of cancer and some non-malignant conditions; and they include statistical data on the results obtained in patients treated in 1937 and earlier years'.

WALL CHART AND CODE FOR LUNGS EXAMINATION.—By H. N. Chatterjee, B.Sc., M.D. (Cambridge, Mass.). Published by P. T. Hall (India), Calcutta. Price, Re. 1-8

IN this chart the author has set forth the methods of clinical examination of the lungs, and its physical signs, and a code for recording the findings (the latter, by the way, is taken from a chart by Dr. Samuel Gee). The list of 'apparatus' (*sic!*) the author wants the student or the practitioner to obtain in order to examine the lungs and the throat is quite formidable: no less than eight items are needed, *viz.* stethoscope, spirometer, cyrtometer, bronchoscopic set, laryngoscope,

chest measuring tape, Mackenzie's diaphragmatic polygraph and concussion pleximeter.

The author has given a long list of 'apparatus', but almost all the physical signs he has enumerated can be elicited by ordinary methods of examination, using less than half the things he has mentioned.

The description of normal and abnormal physical signs is ill-written, and contains half truths and misconceptions. The word 'apex' has been spelt as 'appex' in three different places.

It is difficult to see what useful purpose can be served by this chart.

Abstracts from Reports

ANNUAL REPORT ON THE BERRY-WHITE MEDICAL SCHOOL, DIBRUGARH, FOR THE YEAR 1937-38

It will be recalled that when Major-General Sir Cuthbert Sprawson, Director-General, Indian Medical Service, visited the school and hospital in 1935 he enquired into the staff, equipment and teaching facilities at the school, and embodied the result of this enquiry, together with corresponding data from 27 other medical schools in India, in a tabular statement, which presented the teaching facilities of the various medical schools, not only in relation to each other, but also in relation to an absolute standard, which was defined by the application of certain rules.

The most important deficiencies then noted were:—

The shortage of teaching beds and the low daily average of in-patients in relation to the number of students;

the shortage of staff, particularly the school staff, and to a less extent the hospital staff, and as a consequence, the allocation of the teaching of more than one subject to various teachers;

the lack of clinical material for the teaching of midwifery and gynaecology; and

the want of a sufficient number of microscopes for the teaching of physiology, pathology and bacteriology.

Since the issue of Sir Cuthbert Sprawson's note, substantial progress has been made in remedying some, at least, of the deficiencies, though the standard of the school is still below the average standard of medical schools in India, and falls very far short of the absolute standards, laid down for an efficient medical school by Sir Cuthbert Sprawson.

Considering the several deficiencies referred to above:—

The number of sanctioned beds has been increased from 109 to 131 and the daily average of in-patients has increased from 88 to 98. It is doubtful whether any further increase in the number of sanctioned beds is justifiable, even if funds were made available, as if provided they would be likely to remain empty for the greater part of the year. It would appear that as a result of the establishment in recent years, of well-equipped hospitals in neighbouring tea-gardens, and elsewhere, the number of beds provided is already in excess of the demand, and the disproportion between the student-entry and the number of teaching beds can only be adjusted by reducing the number of annual entrants, a restrictive measure which Government have so far been unwilling to adopt.

The shortage in staff has been reduced by the appointment of a whole-time non-medical teacher of chemistry and physics, and a whole-time teacher of hygiene and medical jurisprudence (an assistant surgeon). This arrangement enables the teachers of anatomy, of medicine and of surgery to restrict their teaching to their proper subjects.

The lack of clinical material in midwifery which, at the time of Sir Cuthbert Sprawson's enquiry, was the most glaring deficiency of all, is now somewhat less apparent: there were in 1934-35 no more than 14 labour cases; in 1935-36 there were 27 and in the year under report 46. This figure is still less than a tenth of the 'standard' number, but the increase is at least encouraging, and is largely due to the opening of the Narsingdas Jallan Maternity and Gynaecological Ward.

The number of gynaecological cases showed a similar gratifying increase.

The shortage of microscopes for teaching purposes has been largely met by the purchase, last year, of 20 new microscopes.

The long list of badly-needed improvements awaiting provision of funds is sufficient evidence of the difficulties under which the school is working and the hostel accommodation for students falls very short of a proper standard; the rooms provided are so cramped and small that serious study must be very difficult, and as there is no separate common room reserved for private study they have therefore no alternative but to use their own huts for the purpose.

The Superintendent, Lieutenant-Colonel C. H. P. Allen, I.M.S., and his staff are to be congratulated on a useful year's work, carried on under conditions which in many respects are makeshift and unsatisfactory for want of adequate funds, adequate teaching material, and adequate accommodation—circumstances which combine to make the measure of success attained the more praiseworthy.

VISWA-BHARATI BULLETIN NO. 25. INSTITUTE OF RURAL RECONSTRUCTION, SRINIKETAN. HEALTH CO-OPERATIVES. BY RATHINDRANATH TAGORE. PRICE, As. 2

This small publication is issued by the above association established some years ago under the presidentship of Sir Rabindranath Tagore, for the mental, moral, and physical improvement of villagers in the Birbhum District of Bengal.

This bulletin gives an account of the public health needs in village communities and how these are being met in a few specially selected villages. At present it is only in the experimental stage, but the results already achieved appear remarkable, and if the principles being instilled into these few villages prove successful and are extended to others the ultimate benefit to the country as a whole should be immense.

The pamphlet does not lend itself to abstraction, but we recommend it to all local government bodies for perusal in the original.

ABSTRACT OF ANNUAL REPORT ON THE RESULTS OF RADIOTHERAPY IN CANCER OF THE UTERINE CERVIX. SECOND VOLUME. EDITED BY J. HEYMAN, STOCKHOLM. LEAGUE OF NATIONS HEALTH ORGANIZATION, GENEVA

The present volume is the second of the series of annual reports on the results of radiotherapy in cancer of the uterine cervix issued by the Health Committee of the League of Nations.

The first annual report, published in 1937, referred to cases treated in 1930 and previous years; the second report includes statements referring to cases treated in 1931.

All five collaborators in the first annual report have submitted statements for the present report and the second report includes three additional collaborators, viz:—

(7) Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York, United States of America (Dr. William P. Healy).

(8) Woman's Hospital in the State of New York, United States of America (Dr. George G. Ward).

(9) Institut du Cancer, Paris, France (Dr. Simone Laborde).

The statements provided by these nine centres vary considerably in respect of the number of years to which they relate and of the number of patients treated yearly in each centre. When all the data included in them are combined, they furnish information concerning 6,570 patients suffering from cancer of the uterine cervix who were examined with a view to treatment, of whom 5,672 (86.3 per cent) were submitted to radiological treatment.

The following tabular statement shows the results obtained after the lapse of five years from the date of treatment:—

		Per cent
Alive without recurrence ..	1,491	26.3
Alive with recurrence (including those operated upon after failure of radiotherapy) ..	102	1.8
Died of cancer ..	3,901	68.8
Died of intercurrent diseases ..	113	2.0
Lost sight of ..	65	1.1
TOTAL ..	5,672	100.0

The 5,672 patients treated were allocated to stages as follows:—

		Per cent
Stage I ..	607	10.7
Stage II ..	1,626	28.7
Stage III ..	2,417	42.6
Stage IV ..	1,020	18.0
Unclassified ..	2	0.04
TOTAL ..	5,672	100.0

Results of treatment calculated for each of the four stages:—

	Number of patients treated	Alive without recurrence	Relative cure rate, per cent
Stage I ..	607	335	55.2
Stage II ..	1,626	590	36.3
Stage III ..	2,417	512	21.2
Stage IV ..	1,020	54	5.3
Unclassified ..	2	0	0.0
GRAND TOTAL ..	5,672	1,491	26.3

The inverse relationship between the proportions of patients allocated to, and cured in, the different stages will be noted.

The patients examined with a view to treatment, but not treated, may be considered in two classes, viz:—

(a) Not treated owing to some condition of the patient such as extent of the disease, general health, or other complication.

(b) Not treated owing to some other reason such as lack of hospital accommodation.

The data needed to divide the whole sample of untreated cases (898 in number) into these two classes have not been recorded; they are available, however, for 198 cases untreated during the years 1930 and 1931, and show that 29 (14.6 per cent) fell into group (a) and 169 (85.4 per cent) into group (b).

The advisory committee invites attention to the steps taken in 1937 to secure greater uniformity in the allocation to stages of cervical cancers and to the definitions of the four stages, namely, the 'Atlas on the division of cancer of the uterine cervix into four stages according to the anatomo-clinical extent of the growth', edited by J. Heyman and published by the Health Organization of the League of Nations. The atlas, which contains 38 diagrams illustrating examples of

the cases to be allocated to each of the four stages, was published in March 1938. It may be obtained on application to the Publications Department of the League of Nations, Geneva, Switzerland.

The committee expresses the hope that the simplified definitions and illustrative diagrams of the atlas will enable experienced clinicians to stage in a reasonably uniform manner those cases in which thorough examination enables the extent of the growth to be precisely determined.

No reference has been made in the report to the possibility that such differences as exist between the cure-rates of co-operating clinics may be related to the methods of treatment used in those clinics. The committee is convinced that consideration of such matters is of small value at present and that it is not yet practicable to assign to differences in methods of treatment, differences in the cure-rates obtained. Work of this kind must be postponed until there is greater certainty that factors, other than the actual treatment used, which are liable to vitiate the reliability of cure-rates stated numerically, have as far as practicable been eliminated. The elimination of such other possible causes of differences in cure-rates constitutes the primary object of the committee's work in its present phase.

The committee renews its invitation made in the first annual report to directors of clinics, and others who are interested in this subject, to communicate with the Chairman, Prof. J. Heyman, Radiumhemmet, Stockholm, with a view to participation in future reports.

BULLETIN OF THE HEALTH ORGANIZATION. VOLUME VII, NOS. 1, 2 AND 3. ANNUAL SUBSCRIPTIONS (6 NUMBERS) 15s.; \$3.75, POST FREE

THE number of Bulletin of the Health Organization of the League of Nations issued in February 1938 contains three articles. The first is the eighth annual review of Reports from Pasteur Institutes on the Results of Antirabies Treatment, by Lieut.-Colonel A. G. McKendrick. The second study deals with field experiments in malaria treatment and prevention carried out in Rumania with synthetic drugs. The third article (by K. Stounnan) deals with an experimental application in the city of Brussels of a system of 'health indices', the purpose of which is to measure the state of health in a given community.

The second number of the *Bulletin* is entirely devoted to the teaching of hygiene, on the basis of a study tour carried out at the end of 1936 by Professors Jameson (United Kingdom), Pittaluga (Spain), and Stampar (Yugoslavia).

The text of the report made by them is given. After a general study of the factors influencing the development and work of the Institutes and Schools of Hygiene in Europe, it describes the principal types of institutes, the recruitment of students and professors, and the organization of the courses. There follow certain general observations on the work of these institutes: full-time service, compulsory training of medical officers, training in hygiene of medical students and graduates, relations with social-insurance institutions, etc. As an annex there is given a detailed description of Institutes or Schools of Hygiene at Ankara, Belgrade, Budapest, Cluj, Jassy, London, Madrid, Nancy, Prague, Rome, Sofia, Warsaw and Zagreb.

The *bulletin* opens with a report on the work of a meeting of Directors of Institutes and Schools of Hygiene which was held from 22nd to 27th November last, mainly to consider the report of Professors Jameson, Pittaluga and Stampar.

The third number of the *Bulletin*, contents of which reveal the wide scope and variety of the work of the Health Organization, includes the report of a committee of experts which was asked to work out a method of assaying the content of morphine in opium and of cocaine in raw cocaine and coca leaves that

would meet the practical requirements of a system of international control over the manufacture of narcotics. It also contains the latest report of the technical commission on nutrition, a report by another group of experts on the problem of insulation and lighting in relation to housing and town planning, and reports on three technical investigations—one into undulant fever in France, another into the significance of cocaine as a habit-forming drug, and the third into the comparative value of certain reactions for the sero-diagnosis of syphilis.

The report on assaying the content of morphine in opium and of cocaine in coca leaves is a further stage in the research work undertaken by the health organization at the request of the committee on the traffic in opium and other dangerous drugs. This report is of a technical character.

The report of the nutrition experts is also of general interest because of the full summary which it gives of the results achieved in investigations on a question which is attracting more and more attention, not only of health administrations, but also of the public. This report describes the state of knowledge concerning the requirements of the human organism in various nutritive elements, including vitamins, and especially during the first year of life. One chapter deals with milk, a foodstuff of the first importance, which must be prevented from becoming the vehicle of infection. Another discusses methods of carrying out surveys on nutrition and on the nutritional conditions of populations, which are essential if any progress is to be made in practical work.

The article on insulation and lighting gives a résumé of the conclusions reached by a special sub-committee of the housing commission of the health organization.

Similar studies have already been made and a report published on the question of noise, cold and heat, etc., in relation to housing.

Enquiries will also be undertaken on urban and rural planning, the abatement of smoke, water supplies, etc.

PROGRESS REPORT ON THE SCHEME OF RESEARCH ON QUALITY IN CROPS WITH SPECIAL REFERENCE TO RICE. DEPARTMENT OF BIOCHEMISTRY, INDIAN INSTITUTE OF SCIENCE, BANGALORE. By DR. A. SREENIVASAN, M.A., D.Sc., A.I.C.

A SUMMARY of this interesting and stimulating report of the work done at Bangalore is given below:—

Parboiled rice.—1. A very large part of the essential nutritive constituents—proteins, minerals and fats, of the husked (unpolished) rice grain—are concentrated in the outer layers, so that the process of polishing which has now become a prevalent practice even in countryside operations of rice pounding and milling, makes the rice almost entirely devoid of nutritive qualities. There is a steady decrease in the percentages of these constituents with milling. The complete removal of the bran layers in the grain results in the loss of about 25, 30 and 60 per cent, respectively of proteins, fats, and minerals.

2. Parboiled polished rice contains somewhat more of nitrogen and phosphorus than raw rice polished to the same extent, provided, however, the rice is not polished to a high degree. At the same time, the difference in composition between raw and parboiled rices is not very much, so that it would appear that the recognized superior quality of parboiled rice is in reality due to its being usually consumed in an under-milled state and to the fact that less of nutritive constituents are lost by the ordinary process of washing and cooking. Analyses of a large number of bazaar samples of raw and parboiled (milled) rices have shown that parboiled rice is less polished than raw rice. The extent to which parboiling preserves the vitamin B₁ and together with it the other essential nutritive constituents of rice on polishing would depend

on the variety of rice and, in particular, the thickness of its bran layer and the extent to which the rice has been parboiled.

3. Parboiling results in a high increase in the yield of head rice on milling. The optimum conditions of parboiling, such as time of steeping, temperature of steep water, time of steaming or boiling and pressure of steam as also the mode of drying, which result in maximum improvement of milling quality have been determined. The improved milling quality on parboiling is a distinct item of advantage to the miller especially when the soft, the *kar* or short-duration and the long-grained varieties, which are known for their poor milling qualities, have to be marketed.

4. The superior milling quality of parboiled rice together with its generally observed high nutritive and antinutritic value (due no doubt to its being milled to a lesser degree than raw rice) should make the production and use of this article more extensive than has hitherto been the case. Parboiled rice even on polishing has a slight yellowish colour. The nature of the factors contributing to the colour of the parboiled grain has been studied and, in the light of the observations, it can be stated that it should be possible, by using certain methods and equipment well suited to the preparation of good parboiled rice, to obtain a product with minimum discoloration.

Chemical composition.—5. There is considerable variation in composition between individual varieties. In particular it has been observed that coloured and coarse-grained varieties of rice contain larger amounts of protein and mineral matter than the fine ones. They also possess very much thicker bran layers, so that, even on milling, the extent of loss of nutritive constituents from such varieties which are considered inferior is less than with the superior varieties under ordinary conditions.

6. The possibility of increasing the protein and mineral contents of the rice grain by judicious control of fertilizer applications has been indicated from analyses of rice grown under different manurial treatments.

There is a great need for popularizing the consumption of unpolished rice, especially from coloured and coarse varieties. Such rices often compare favourably with wheat which has held a place of pre-eminence among cereal foods.

Keeping quality.—7. The factors affecting the keeping quality of rice have been determined and it has been shown that the poor keeping quality of unpolished rice is essentially due to the rice oil contained in the embryo and the outer integuments of the grain. It is possible, by suitable control of humidity and storage methods, to prevent or, at any rate, greatly minimize the deterioration of hulled rice on storage, but further efforts should be made to improve the keeping quality so as to be readily applicable in practice. Parboiled rice has got much better keeping quality than raw rice, even when unpolished.

Fumigation of rice.—8. Disinfection of rice consignments with sulphur dioxide appears to affect the quality of the product although not to a considerable extent. Such rice cooks to a pasty condition and the cooked product has a distinct acidic taste. Some of the factors that control the ill-effects of fumigation have been studied.

Digestibility.—9. The rate of starch hydrolysis in the different varieties of rice, both raw and parboiled, increases with increased polishing. Rice bran has a definite, though small, inhibiting action on the activity of the digestive ferments. The lower *in vitro* digestibility of unpolished rice may not be of great significance in practice. Parboiling results in partial dextrinization of the rice starch so that under ordinary conditions, where proper penetration by the enzymes is ensured, such rice is more easily digested than raw rice.

Storage of rice.—10. Freshly harvested rice cooks to a pasty condition and storage improves the swelling capacity of the grain on cooking. The different methods of storage as affecting the cooking quality of

rice have been studied and, in future work, attempts should be made to hasten storage by suitable treatments.

11. The changes in the amylases of the rice grain during ripening and storage have been followed and the possible bearing of these results on the storage changes are being investigated. The nature of the changes in rice starch as a result of storage is also being studied.

Nutritive value of rice varieties.—12. From results of extensive feeding experiments with different rice varieties using young rats and pigeons, it has been shown that growth is essentially correlated with composition, particularly protein and mineral contents of the rice samples. Coloured and coarse varieties induce better growth in animals, on account of their higher protein and mineral contents. One of the factors determining growth rate appears to be the level of protein supply and in this connection it is important to determine the supplements needed to make rice a wholesome diet. The availability of the different constituents of rice and the means of increasing them are under study. The effect of parboiling and of polishing on rate of growth with young rats is also being followed.

13. The chemical composition and nutritive value of rice varieties grow under (1) irrigated, transplanted, (2) irrigated, broadcast, and (3) dry broadcast conditions have been studied. Dry cultivated paddy has been shown to be least nutritious compared to wet cultivated rice. Irrigated broadcast rice is intermediate in composition and nutritive value between the dry and wet cultivated rice.

GENERAL CONCLUSION

It is generally argued by dietetic experts that rice is a poor article of diet and that it is not possible to alter its food value appreciably. It has even been suggested that rice should, in part at least, be substituted by some other cereal like wheat. In the present investigations, it has been shown how it is possible under certain conditions to enhance greatly the nutritive value of rice as ordinarily consumed. Thus, although the fine and the white varieties of rice are generally favoured by consumers, it has been found that some of the coarse-grained and coloured varieties contain larger quantities of protein and mineral constituents, particularly phosphorus, calcium and iron. Again, the losses in nutritive constituents as a result of washing prior to cooking of rice is not generally recognized so well and may be quite considerable especially when reckoned with the losses on polishing. Although washing with water removes adhering dirt from the grain, it is generally resorted to often only with a view to obtaining a whiter product on cooking; it should therefore be possible to avoid this wasteful process by adopting some system of dry-cleaning such as sieving and winnowing. There is great need for educating the public in regard to (a) the use of unpolished rice especially from coloured and coarse varieties known to be rich in essential nutritive constituents and (b) changes in ordinary cooking practice which will result in minimum loss of these constituents.

It is possible, by proper fertilizer applications, to enhance the nutritive value of rice, by enriching its protein and mineral contents, sometimes to the extent of 20 per cent. There is need for research to be directed on co-operation with breeders, towards the development of grains which are naturally rich in composition and have a high nutritive value.

Rice is a crop of the country and a very large number of good yielding varieties have been evolved at the different breeding stations. The farming practices are very familiar to the agriculturist. Rice protein has a high biological value, higher than that of wheat and, as indicated above, with certain varieties, its composition compares favourably with that of wheat. Attempts should therefore be concentrated on improving its general quality.

SOME PROBLEMS OF PRACTICAL IMPORTANCE, FOR IMMEDIATE STUDY

Rice varieties from different parts of India, which are naturally rich in composition, should be examined for their general nutritive value. In view of the fact that coloured and coarse grains are more nutritious, this observation should be extended and confirmed with a large number of rice varieties from all over the country. The types of rice of high nutritive value which can be grown under different soil and climatic conditions should also come in for detailed study.

Having chosen varieties with high nitrogen and phosphorus contents attempts should be made to increase its food value still further by suitable manurial applications. Preliminary observations have shown that under certain conditions the composition of the grain can be enriched to the extent of 20 per cent, but further work on this is necessary.

Since the present work has shown that the nutritive value of rice is essentially related to its protein and phosphorus contents, work should be undertaken with a view to comparing and improving on the quality of the proteins of rice varieties. There is also need for studying the influence of nitrogenous manuring on the composition and nitrogen distribution of the proteins of the grain.

A large part of the phosphorus in rice is present as phytin which, as has been shown by a number of recent investigators, is ordinarily unavailable to the human system. There is no doubt, however, that the culinary practices greatly influence the availability of the phosphorus compounds. The ratio of calcium to phosphorus in rice is also very low and hence supplements of calcium in the form of vegetables and other food articles will also favourably influence phosphorus assimilation. The extent of availability of the phosphorus compounds in rice under different conditions and means of increasing the same will have to be studied in detail.

Evidence obtained already would show that nutritive value is determined more by composition than by the duration of the crop. Further examination of a large number of long and short duration crops should be made with a view to verifying this observation.

Again, contrary to the popular belief and the evidence adduced by McCarrison, it has been shown that dry cultivated rice is nutritionally inferior to irrigated rice. It is necessary to extend and confirm these observations with other varieties and over extended periods.

Unstored, freshly harvested rice is unfit for consumption as it cooks to a paste and is not easily digested. Preliminary work has shown that it is possible to hasten artificially the period of storage necessary before the rice could be made fit for consumption. The nature of the factors responsible for improved cooking quality and digestibility on storage should be examined further with a view to evolving a practical method of hastening storage changes.

The main feature which distinguishes rice from most other cereals is that it is predominantly consumed in the milled state. Although unmilled rice does not find favour among consumers chiefly on account of its unattractive appearance, yet the real difficulty in regard to its use is that it has a very poor keeping quality. Hulled rice in the unpolished condition undergoes rapid deterioration with the development of off-flavours on keeping. The exact nature of the changes on storage should be studied in detail and the conditions determined under which unpolished rice can be stored in practice without deterioration. Such a study will be of great economic value and help to popularize the consumption of unpolished rice. There is evidence to suggest that parboiling improves the keeping quality of rice even in the unmilled condition, but further work is essential.

In this connection, it will also be highly desirable to devise cheap and efficient hand-hullers which can be used continuously without appreciable wear and in small households.

ANNUAL REPORT ON THE WORKING OF THE RANCHI INDIAN MENTAL HOSPITAL, KANKE, IN BIHAR, FOR THE YEAR 1936. By LIEUT.-COL. J. E. DHUNIBHOY, M.B., B.S., I.M.S., SUPERINTENDENT

The hospital continues to receive patients from the Provinces of Bengal, Bihar and Orissa.

The sanctioned accommodation of the hospital is for 1,013 males and 272 females. The 50 additional emergency beds, sanctioned by Government in 1929 to relieve overcrowding in the male section, having been found insufficient, it was proposed to increase the accommodation by another 14 beds, and the Government were pleased to sanction the increase by another 14 beds from the 1st October, 1936.

The apparent increase in the daily average number of sick patients treated during the year 1936 as compared to 1935 and 1934 is due to the general increase in the hospital population during the year under review and not due to any increase of illness.

The number of mentally defective children is steadily going up and in the absence of a separate children's ward it is becoming increasingly difficult for the administration to house and treat such children. During the year under review a very inexpensive scheme for the conversion of one of the existing spare occupational therapy buildings in the female section into a children's ward was placed before the managing committee of the hospital for approval. It was unanimously accepted by the committee and the final sanction of the Government to the scheme is now awaited. A mental hospital is not a fit place for treatment of certified mentally defective children and in the absence of proper homes for mentally defective children as well as of the Mental Deficiency Act for India, the magistrates have no other alternative but to admit them for treatment in the mental hospitals. It is therefore clear that some measure of reform is badly needed in this direction.

The care and treatment of insane to-day in a modern mental hospital can only be fully appreciated by a comparison with conditions which existed in the one time old asylums of India. A visit to the Ranchi Indian Mental Hospital cannot fail to convince an unbiased person of the complete hygienic and favourable conditions which exist. A modern mental hospital is a self-contained unit and in its communal life the patients find everything they need and no effort is spared to make their daily lives as happy, comfortable and contented as is possible having regard to the distressing mental conditions from which many of them suffer.

As stated in previous reports 'Occupational therapy' is and always will remain a sheet-anchor of our treatment. Under its beneficial influence noisy and turbulent wards of the hospital are fast disappearing and a number of hypnotic draughts given at night is considerably reduced. A brief outline of work done in Occupational Therapy Classes of this hospital is given below:—

Weaving, carpentry, smithy, cane and bamboo work, painting, tailoring, embroidery and lace work, gardening, shoe-making and mending, joss-stick-making, etc.

Besides, several patients are employed in the kitchens of both the sections and wards to help in cooking and general ward work.

Last year also when on leave I visited all the best known centres on the Continent and England. I am glad to be able to state that the 'Occupational therapy' classes of the Ranchi Indian Mental Hospital can stand a fair comparison with those of the hospitals I visited.

An institution well equipped with means for the various forms of hydrotherapy is well on the road to practically complete abolishment of the use of sedatives for highly excited patients. This most useful form of therapy was given to several patients throughout the year under report. Altogether 176 male and 44 female patients were given this treatment with very

gratifying results. The average number of hours of immersion of patients was 104.88.

Sulfosin therapy.—During the year under report 83 patients were treated with sulphur injections. The results were very good as the treatment effected recovery in 12.05 per cent and improvement in 66.27 per cent of cases.

Use of sulphur injections in skin diseases.—During the year under report, 20 patients suffering from the skin affections were treated with sulphur injections and as in the past our results were very encouraging as all the cases improved after 5 or 6 injections.

Evipan sodium.—This drug was tried in a few cases of acute excitement where other drugs failed to quieten the patients and to induce sleep. In some it worked like a charm and the patients remained quiet from 24 to 48 hours after an injection.

Rauwolfia serpentina.—A further supply of an alcoholic extract of this drug (Hindi—*Chota chand*—or what is popularly known as Hassan Imam's root) was received during the year under report from the Calcutta School of Tropical Medicine and was tried on patients, but the results were rather disappointing.

Bacilicum citratum or Subji leaf (Bisva tulsi).—The leaves of this plant contain yellowish green essential oil and 5 to 6 drops of this oil after pressing of the leaves if poured in each nostril of an excited patient allays excitement and serves at times as a powerful hypnotic. A further experiment on a larger scale was made with this drug during the year under report and the results were rather disappointing. The drug acted as a hypnotic in two cases only and the majority remained unaffected by it.

Malaria therapy.—The malarial treatment for general paralysis was continued during the year under report. It is nearly always difficult successfully to re-infect those who have had previous attacks of malaria.

Convulsion therapy by the drug cardiazol.—In 1935 when in Budapest, I was invited by Dr. Ladislaus v. Maduna, M.D., of the Royal Hungarian State Mental Hospital, to see this novel treatment of schizophrenia evolved by him. The drug immediately produces a typical epileptiform attack in the patient like that of major epilepsy. On my return I selected 12 typical cases of schizophrenia for experiment and my results are as follows:—

Stationary or not improved	Improved	Recovered
5	4	3

Games and amusement.—As in the previous years the amusement halls of both the sections were crowded with patients each evening either for music, indoor games, cinemas or theatricals and the hospital band was in attendance daily.

A number of patients assemble every afternoon on the hospital play-grounds and take part in outdoor games.

Outings.—Both male and female patients were taken out in batches daily for motor drives to Ranchi and those who were able and desirous to do their own shopping in the town were allowed to do so.

Parole.—A number of patients were granted local as well as Ranchi parole and not one of them abused the privilege so granted.

ANNUAL REPORT OF THE CALCUTTA MATERNITY AND CHILD WELFARE COMMITTEE, 1937

At the end of 1936 it was decided to change the method of work of the four Red Cross Maternity and Child Welfare Centres in Calcutta. The plan of work adopted was the same as that followed in the model Maternity and Child Welfare Centre attached to the All-India Institute of Hygiene. Work on those lines began from 1st January, 1937. The new method worked well, and the year closes with the expectation that the health of the women and children living in the selected areas will so improve as gradually to raise the standard of health of the communities living there.

Dr. Neal, W.M.S., Acting Professor of Maternity and Child Welfare at the All-India Institute of Hygiene, rendered invaluable help in launching the new method of work. She arranged short refresher courses which were attended by the Red Cross health visitors in January, February and March. It was invaluable for the health visitors to have the opportunity of living and working in the Institute Centre and of thus seeing in operation the plan they were being asked to follow in their own centres.

TRIENNIAL REPORT ON THE WORKING OF THE CIVIL HOSPITALS AND DISPENSARIES IN THE PROVINCE OF ASSAM FOR THE YEARS 1935, 1936 AND 1937

In spite of the financial stringency there was, during the triennium, appreciable progress in the extent of medical relief offered in public and private hospitals and dispensaries. The number of institutions increased by 21 making a total of 281 hospitals and dispensaries of all kinds functioning at the end of the period. The largest increase, viz, 13, naturally occurs under the head 'Local Fund Dispensaries' which accounts for nearly two-thirds of the total number of institutions. Of these, Kamrup was responsible for 5, Darrang and Lakhimpur 2 each and Nowgong, Goalpara, Sylhet and Cachar 1 each. Two state dispensaries were opened—one in the Naga Hills at Ghukhya and another in the Garo Hills at Bajengdoba. The rest of the 21 dispensaries are made up of departmental, railway and private dispensaries.

Along with this there was, during the period, also an increase of 151 beds, the majority of which were reserved for women. Apart from the Ganesh Das Red Cross Hospital for women and children at Shillong—which represents one of the chief achievements of the period—maternity or female wards or blocks were opened at various places. Simultaneously with increase in the accommodation, better nursing was made available at several district town hospitals in the plains. These results were largely due to private philanthropy and Government join the Inspector-General of Civil Hospitals in extending their warmest thanks to those who helped in this most desirable advance.

The increased and improved facilities provided for in-door medical treatment naturally resulted in a large increase in the number of in-patients who numbered 80,620 as compared with 63,600 in the preceding triennium. The out-door attendance, however, in spite of the increase in the number of dispensaries, shows a slight fall.

Kala-azar.—The persistent increase in the number of kala-azar patients in spite of the efforts of the public health department is a clear warning against any relaxation in the campaign waged against it.

Tuberculosis.—Tuberculous cases increased by about 20 per cent. Little has so far been done to tackle this disease in this province. There is no sanatorium nor even a clinic except the one recently opened at Shillong. Departmental activities have till now been confined to propaganda by means of lectures and demonstrations with the help of magic lanterns. It is realized that this is not enough and Government have recently ordered that the public health department should go a step further and advise those cases that come to their notice regarding proper treatment and precautions. Examination of sputa, free of charge, has in other countries been found to be an essential step in combating this disease. Government are now proposing to make a beginning with this in those hospitals and laboratories which have the necessary staff and equipment and gradually to extend it to other hospitals when it is possible to provide these with the necessary staff and equipment.

Leprosy.—This malady is receiving an increasing amount of attention in some parts of the Province. Besides the new Municipal Leper Asylum at Gauhati which came into existence in 1934 the number of centres constructed mainly out of the contributions

from the Assam Branch of the British Leper Relief Association increased by 20. Otherwise, there was no change in the number of institutions where this disease is treated or in the method of treatment.

Yaws.—This disease is fairly widespread in Lower Assam and is engaging the attention of the public health and the medical authorities. The increase of 3,292 cases under this head is largely the result of the intensive campaign leading to the detection and treatment of more cases.

Malaria.—Malaria continued to occupy the best part of the activities of the Assam Medical Research Society. Apart from investigation into anti-larval measures, malaria surveys and village treatment schemes with cinchona febrifuge financed by Local Boards and Government, the society evolved in co-operation with the public health department and the provincial advisory malaria committee 19 anti-larval and 5 treatment schemes after completing a survey. The short courses in malariology run by the society were availed of by Government, tea gardens and local bodies.

ANNUAL REPORT OF THE EXECUTIVE HEALTH OFFICER FOR THE CITY OF BOMBAY FOR THE YEAR 1937

The conditions of public health of the city during the year were satisfactory. The number of live births registered during the year was more by 4,687 than the number of deaths. This excess of births over deaths was equivalent to 4.0 per 1,000 population calculated on the census of 1931 and was recorded seven times in succession. Before 1931 there was no such excess since 1866, the year in which birth records were instituted.

Compared with the decennial averages (1927–36) the total number of deaths shows an increase of 3,690, the principal increase in the mortality being 1,496 under respiratory disease, 356 under tuberculosis, 323 under congenital debility and diseases of early infancy, 268 under smallpox, 219 under diarrhoea and enteritis, 180 under dysentery, 142 under enteric fever, 106 under cerebrospinal fever, 30 under diphtheria, 332 due to old age and 90 due to violence.

On the other hand there was decrease in the deaths under acute and remittent fever by 109, under malarial fever by 91, under puerperal state by 41, under cholera by 26, under leprosy by 18 and under influenza by 14.

The deaths among infants under one year of age numbered 8,688, being 258 less than in the preceding year and 1,015 more than the annual average in the decennium 1927–36. The infant mortality rate expressed as the number of deaths in infants per 1,000 registered births was 245.0 for the year 1937. The lowest rate was 218 registered in 1932.

The number of municipal nurses employed is ten, one being attached to each of the ten district registrars' offices. They visit daily the localities and the chawls inhabited by the poor and help to diffuse and popularize elementary knowledge of the principles of health and hygiene and to carry such knowledge into the homes and lives of the ignorant; they give advice on the prevention of disease and the care and upbringing of infants and bring to the notice of the authorities unregistered births, unvaccinated children and cases of sickness; they also persuade prospective mothers to go to the maternity homes provided for them free. Where this provision is not taken advantage of, they attend on the women in their own houses providing them with bedding for their confinement, and with food in shape of milk and bread during the first seven days of the puerperal period. The visits of the nurses are frequently the means of bringing to the municipal dispensaries sick persons who would otherwise either not know the existence of the facilities provided or knowing them would, through indifference and apathy, neglect to benefit by them. These visits are doing much good and are welcomed and appreciated by those for whose benefit they are paid.

Service Notes

APPOINTMENTS AND TRANSFERS

Lieutenant-Colonel N. C. Kapur made over charge of the Burdwan Jail to Major K. S. Fitch on the forenoon of the 7th November, 1938.

On return from leave Lieutenant-Colonel C. M. Nicol resumed charge of the office of the Director of Public Health, Punjab, on the forenoon of the 6th December, 1938.

Lieutenant-Colonel A. D. Loganadan, Assistant Director of Public Health, Central Range, Lahore, reverted to the Military Department, with effect from the forenoon of the 6th December, 1938.

Lieutenant-Colonel H. Aung Khin was appointed Civil Surgeon, Rangoon (West), *vice* Lieutenant-Colonel J. H. Barrett, from the afternoon of the 17th December, 1938.

Lieutenant-Colonel D. P. McDonald on return from leave was appointed First Surgeon, Rangoon General Hospital, *vice* Lieutenant-Colonel H. Aung Khin, from the afternoon of the 17th December, 1938.

Lieutenant-Colonel J. H. Barrett was appointed Civil Surgeon, Toungee, *vice* Major P. A. C. Davenport, from the forenoon of the 23rd December, 1938.

Subject to the approval of the Secretary of State for India to the transfer to the Civil Branch of the Indian Medical Service of Major W. F. Cooper, that officer is appointed as a leave reserve officer under the Central Government and is attached, until further orders, to the office of the Port Health Officer, Bombay, with effect from the 9th November, 1938.

The services of Captain P. I. Franks are placed at the disposal of the Government of Bengal for employment as Surgeon to His Excellency the Governor of Bengal, with effect from the 11th April, 1938.

Captain G. P. Charlewood, Civil Surgeon, Coorg, is temporarily appointed to officiate as an Agency Surgeon, with effect from the forenoon of the 29th November, 1938, and is posted as Residency Surgeon, Mysore, with effect from the same date.

Captain F. C. Leach, whose services have been placed at the disposal of the Government of the C. P. and Berar, is attached to the office of the Civil Surgeon, Nagpur, for training at the Mayo Hospital and Central Jail, Nagpur, from the 6th December, 1938.

The undermentioned appointments are made:—

To be Lieutenants (on probation)

1st November, 1938

Frederick William Sneddon, with seniority 1st November, 1937.

Ross Morrison McCullough, with seniority 1st November, 1937.

Harry Victor Morris, with seniority 1st November, 1937.

Albert Steven Brown.

LEAVE

Colonel E. G. Kennedy, Deputy Director-General, Indian Medical Service, is granted leave on average pay for 3 months and 4 days, with effect from the 16th January, 1939. His services are placed at the disposal of His Excellency the Commander-in-Chief on the expiry of the leave.

Lieutenant-Colonel J. B. Hane, O.B.E., an Agency Surgeon, is granted leave on half-average pay for 33 days, with effect from the forenoon of the 29th November, 1938.

Lieutenant-Colonel J. M. Shah, M.B.E., Specialist in Venereal Diseases for the Bombay Presidency, has been granted leave for 25 months and 16 days from 1st December, 1938, preparatory to retirement, with effect from 17th January, 1941.

PROMOTIONS

Lieutenant (on probation) to be Captain (on probation)

C. W. Greene. Dated 16th May, 1938, with seniority from 1st January, 1938.

G. A. Graham. Dated 28th September, 1938, with seniority from 1st May, 1938.

D. McC. Black. Dated 28th September, 1938, with seniority from 1st May, 1938.

J. G. Fife. Dated 28th September, 1938, with seniority from 1st May, 1938.

N. D. Jekyll. Dated 28th September, 1938, with seniority from 1st May, 1938.

J. H. Biscoe-Smith. Dated 28th September, 1938, with seniority from 14th August, 1938.

A. C. Glendinning. Dated 28th September, 1938, with seniority from 31st August, 1938.

G. C. Retz. Dated 12th October, 1938, with seniority from 1st July, 1938.

A. R. Woodforde. Dated 12th October, 1938, with seniority from 18th July, 1938.

R. D. D. Birdwood. Dated 1st November, 1938.

The seniority in the rank of Lieutenant of Captain (on probation) B. J. Doan is antedated to the 1st May, 1936.

The seniority of Lieutenant (on probation) R. Pasmore is antedated to the 2nd March, 1937.

RETIREMENTS

Colonel G. R. Lynn, D.S.O. Dated 1st December, 1938.

Lieutenant-Colonel J. L. Sen, M.C. Dated 22nd October, 1938.

Lieutenant-Colonel N. B. Mehta. Dated 5th November, 1938.

Lieutenant-Colonel R. E. Wright, C.I.E. Dated 14th November, 1938.

Lieutenant-Colonel P. C. Banerjee. Dated 5th January, 1939.

Notes

M & B 693 IN GONOCOCCAL INFECTIONS

We have received from Pharmaceutical Specialists (May and Baker), Limited, a copy of another publication on that remarkable addition to chemotherapy, M & B 693. This 16-page booklet, which is entitled 'M & B 693 in Gonococcal Infections', is a complementary publication to 'M & B 693 in Pneumococcal Infections', and 'M & B 693 Biological and Biochemical Data'.

We understand from the manufacturers that they delayed bringing M & B 693 to the notice of venereologists until they were satisfied that the use of this product marked a real advance in the chemotherapy of that disease. This booklet which they have now produced represents the pooled results of observations in over 1,000 cases.

Copies of this publication are available to medical practitioners on request.

THE DOCTORS' CAR—OPEL

No class of professional men in the country finds a motor car so indispensable as medical men. In cities, of course, a car is as necessary to a doctor as a stethoscope, while in the small towns, mofussil districts, and throughout the huge tea and coffee planting areas of India, a doctor without a car is handicapped almost as much as one without patients.

Many thousands of medical men, with small practices, or resident in very competitive localities, find the upkeep costs of a car makes a big hole in their nett revenue, and to these in particular a few details of what is, in fact and practice, the most economical light car on the market should be of value.

A doctor's car has got to be smart and look smart and above all be as economical as it is dependable. It must not swallow fees in the form of excessive petrol consumption; it must be ready to start off on a long run over rough country at a touch on the starter, and take its owner at any reasonable sort of high speed on his rounds or to and from an urgent call.

To conform to these elementary requirements is to ask the least of an OPEL. Here's a quality-car built to do more than come and go, which any car does. OPEL does every journey with an eye to travel-comfort—ensured by even more built-in factors than its outstanding knee action front wheel suspension.

There are small models to choose from, the 10, 12 and 16. The first two are 4-cylinder cars, with 92- and 96-inch wheelbases respectively, the third is a 6-cylinder car, developing proportionately greater h.p. and having a wheelbase of 104 inches.

THE TREATMENT OF CHRONIC TONSILITIS By SUCTION AND IRRIGATION

THE method of treatment is similar to that described by Mr. E. A. Peters in his book 'Tonsils and Nasopharyngeal Sepsis' and is specially useful in cases of middle-aged patients and adults who wish to postpone or avoid enucleation of the tonsils, it affords immediate relief and diminishes focal sepsis.

The instrument described is for applying negative pressure and supplying a stream of antiseptic solution to the tonsils alternatively, it is used in connection with either an electric or hydrostatic suction pump and has the great advantage of being easily operated with one hand, leaving the other free for the use of a tongue depressor.

The instrument which I have designed has proved most satisfactory in use: it consists of a hollow metal handle which also acts as a water-tight container for antiseptic solution (water or colloidal iodine), near to the top of the handle is an air-hole, situated immediately below a conveniently-placed press button, both air-hole and press button can be operated simultaneously by pressure of the ball of the thumb. To apply vacuum the air-hole is closed, to flush the tonsil under pressure the air-hole is kept closed and the button is pressed at the same time.

Attached at a right angle to the handle is a metal tube of suitable length fitted with a conveniently placed mount to connect to the rubber tube of a suction apparatus; at the distal end of the metal tube is a flexible rubber tube joint and a glass suction cup to apply to the tonsil, the rubber joint allowing freedom of movement for application of the cup; the cups are of various sizes and interchangeable, the particular case being treated and being transparent the tonsil can be kept under observation during treatment. Further, the treatment can be carried out without the use of a local anaesthetic in most cases.

The instrument is made by Messrs. Down Bros., Ltd., London.

GEORGE BOTROS,
Cairo.

BAYER REMEDIES LIMITED

THE medical profession is requested to note that a Company started operations on 1st January, 1939, under the style of Bayer Remedies Limited with its registered office in Bombay and branches in the principal

provinces of India. The company has been registered under the Indian Companies Act, with a capital of Rs. 30,00,000 of which Rs. 20,00,000 is subscribed and paid up. The company having been constituted as a private limited company with Messrs. Haverro Trading Company, Limited, incorporated in Rotterdam (Holland) as one of its important shareholders, no shares will be offered, for an initial period, to the public at large.

Bayer Remedies Limited will handle all the pharmaceutical, sero-bacteriological, chemical, dental and veterinary preparations manufactured by 'Bayer' as well as 'Behringwerke' of I.G. Farbenindustrie Aktiengesellschaft, Germany, and hitherto handled in India, Burma, Ceylon and Afghanistan by Messrs. Haverro Trading Company, Limited.

The company is a sign of India's growing importance in international commerce and trade. But it has also a definite purpose to fulfil. Most of the present-day pharmaceuticals are too complex to be efficiently handled by a general mercantile firm such as Haverro's. Their handling (storage, distribution, directions for use, etc.) calls for a highly specialized body equipped for technical service and backed by continuous research. To these matters the company wishes to devote its exclusive attention.

The services of most of Haverro's experienced staff having been secured by Bayer Remedies Limited, and the products being guaranteed by the same well-known Bayer cross, the company fervently hopes to secure the same confidence and co-operation of the medical profession in this country as hitherto enjoyed by Messrs. Haverro Trading Company, Limited.

Publishers' Notice

SCIENTIFIC Articles and Notes of interest to the profession in India are solicited. Contributors of Original Articles are entitled to receive 25 reprints *gratis*; additional reprints can be obtained on payment. No reprints will be supplied unless contributors ask for them at the time of submitting their manuscripts.

Communications on Editorial Matters, Articles, Letters and Books for Review should be addressed to THE EDITOR, *The Indian Medical Gazette*, c/o The Calcutta School of Tropical Medicine, Central Avenue, Calcutta.

Communications for the Publishers relating to Subscriptions and Advertisements should be addressed to THE PUBLISHERS, *The Indian Medical Gazette*, P. O. Box No. 54, Calcutta.

Annual Subscription to '*The Indian Medical Gazette*', Rs. 16 including postage, in India. Rs. 19-8 including postage, abroad. Single copies Re. 1-8 each. Back numbers (if available) for the previous year Rs. 2-8 each, and all other back numbers Rs. 5 each.

Subscribers who so desire may have their copies packed flat in a strong envelope. The extra charge per annum is Re. 1-8 which should be added to the subscription. The envelopes are strongly made, and the *Gazette* is not folded, nor creased, in transit.

Papers and articles forwarded for publication are understood to be offered to *The Indian Medical Gazette* alone, and any breach of this rule will be followed by non-publication. When any such article appears in the *Indian Medical Gazette*, the copyright automatically becomes the joint property of the author or authors, and of the publishers.

The Editors of *The Indian Medical Gazette* cannot advise correspondents with regard to prescriptions, diagnosis, etc., nor can they recommend individual practitioners by name, as any such action would constitute a breach of professional etiquette.

SOME NOTES ON CLINICAL HEART DISEASE*

By GERARD KELLY, F.R.C.P. (L)

MAJOR, I.M.S.

Professor of Clinical Medicine, Medical College Hospitals, Calcutta

I HAVE compiled these few notes in order to indicate to the general practitioner something of the real substance of heart disease: there is nothing in them for the specialist.

Partly by choice and partly by request I have included a few remarks on the following:—

1. The problem or problems of the cardiovascular dysfunction case.
2. Heart failure—
Left-sided heart failure.
Right-sided heart failure.
Mixed failure.
3. Symptomatology—
Dyspnoea.
Pain.
Palpitation.
4. Neurocirculatory asthenia.
5. Auscultation.
6. The estimation of blood pressure.
7. Radiography of the heart and aorta.

THE PROBLEM OR PROBLEMS OF THE CARDIO-VASCULAR DYSFUNCTION CASE

A patient complaining of symptoms of cardiovascular dysfunction presents for your appreciation one or more of the following problems:—

1. Is he a neuropath or a cardiopath?
2. If a cardiopath, is there evidence of failure or impending failure, and to what extent is the heart incapacitated?
3. If a patient is a cardiopath, it does not follow that all the symptoms are due to the heart. There may be a neurotic element. That is to say—a patient may be both a cardiopath and a neuropath: if so, what is the responsibility of each factor in the case?

'The cardiopath tends to become a neuropath'—Mackenzie. Actually, many cardiopaths tolerate their disablement with great fortitude, but a proportion only, often those with but little cardiac damage, suffer more from psychoneurosis than heart. A very occasional cardiopath may proclaim his psycho-neuropathy by addressing his doctor as if the doctor had given him his disease.

We shall refer very briefly to the commoner mechanisms, left-sided and right-sided failure.

When we speak of left-sided failure, *e.g.*, hypertensive heart failure or failure of the left ventricle behind high systemic blood pressure, we visualize adequate filling but inadequate emptying of the left side of the heart with corresponding increase in its size. Our conception of right-sided heart failure, *e.g.*, failure of the right ventricle behind mitral stenosis or behind chronic bronchitis and emphysema is precisely similar.

Just over a century ago an English physician, James Hope, inspired by the work of Corvoisart, evolved the 'back-pressure theory' of cardiac failure. 'As an obstacle to the circulation', he said, 'operates on the heart in a retrograde direction, the cavity situated immediately behind is the first to suffer from its influence'. Otherwise stated, congestion back of the failing chamber is the cardinal feature of congestive failure rather than inadequate output of the failing chamber. This rediscovery of Hope's

Heart failure.

Diagram illustrating the back pressure theory of congestive (left-sided and right-sided) heart failure.

vital observation is a recent landmark in the study of heart failure.

LEFT-SIDED (CONGESTIVE) HEART FAILURE

This is the commonest of all forms of heart failure. Its causes are left ventricular defeat by overstrain and disease of the left ventricle, namely, hypertension, coronary disease (arteriosclerotic or syphilitic) and valvular disease (aortic regurgitation or stenosis and mitral disease with preponderant regurgitation). Pulmonary hypertension or a rise of pressure in the pulmonary circuit behind the failing left ventricle constitutes the first stage of left ventricular failure. This is manifested clinically by an accentuated pulmonic second sound, by dilatation of the pulmonary vessels seen in the lung roots of the radiogram and by mitralization of the heart radiologically, owing to the enlargement of the pulmonary conus of the right ventricle behind the pulmonary hypertension. In the next stage there is transudation from the engorged vessels with the production of pulmonary oedema, often paroxysmal later persistent. Hence the classical symptoms of left-sided failure are effort dyspnoea and cardiac asthma both of which own the same

* Being a paper read at the Calcutta Medical College Reunion, 1938.

fundamental mechanism, i.e., pulmonary congestion and œdema. The most ominous signs of left-sided failure are gallop rhythm and pulsus alternans which may be combined with cardiac asthma to form the gravest trilogy in the domain of heart disease. Negativity of T in lead I of the electro-cardiogram is of correspondingly evil prognosis. A widened low voltage and usually a bifid or flat-topped P-wave have recently been described by Wood and Selzer as an early sign of left ventricular failure.

Left ventricular failure is usually a passing phase, for the increased resistance in the lungs soon stresses the right ventricle which fails in turn thereby relieving somewhat the symptoms of left ventricular failure. While the phase of left ventricular failure lasts there is no œdema nor venous congestion, although pulmonary hypertension and even pulmonary œdema are present and periodic attacks of nocturnal dyspnoea occur. Even hydrothorax may occur at this stage before the right ventricle fails. Much less commonly the ventricular imbalance of a forceful right ventricle and a failing left ventricle may be long maintained to the greater respiratory distress of the patient; this form of left ventricular failure is sometimes improperly called 'dry failure', a term that more correctly describes a right-sided congestive failure dehydrated by salyrgan.

Coronary thrombosis is a combination of left heart failure and of peripheral circulatory failure. When the usual clinical sequence obtains in a case hitherto free from congestive failure, the first phase of coronary thrombosis is marked by pain or dyspnoea and by shock, whereas the second phase, denoted by the offset of shock, is characterized by the appearance of congestive failure. In any case, the greater the shock the less apparent is cardiac failure and *vice versa*. In shock the heart's income is reduced to an extent which is unembarrassing even to the grossly infarcted heart. With the passage of shock, however, the venous income increases and the failure of the left heart to rise to the occasion is soon translated to the right heart in terms of congestive failure.

In pure left ventricular failure the rhythm is regular. The inquiry of Parkinson and Clark-Kennedy in 1926 regarding failure with normal rhythm established that 'there is an important relation between the pathological basis for a cardiac disease and failure and the absence of fibrillation. In general, auricular fibrillation was the rule in rheumatic heart disease and goitre, while failure with normal rhythm was the rule in hypertension, coronary disease and emphysema'. It is also the rule in cardiovascular syphilis. In the latter ætiological groups, ventricular strain and disease cause the ventricles to give way before the auricles have reached the stage of fibrillation. Gavey and John Parkinson remind us that 'apart from the factor of rhythm and the factor of specific pathology conditioning rhythm, there is a third factor of

the heart-rate. A regular rhythm failure may occur with a normal or moderate ventricular rate, or a high rate'. Failure with normal rhythm may be more serious than when auricular fibrillation consorts with failure. Gavey and John Parkinson's recent investigation regarding the clinical value of digitalis in heart failure with normal sinus rhythm reveals the following pertinent facts: 'In heart failure with normal rhythm digitalis is helpful in rather more than half the cases. In heart failure with auricular fibrillation, digitalis is more often helpful than it is in normal rhythm, for it benefits more than two-thirds. The real difference in the response of heart failure to digitalis lies not between auricular fibrillation and normal rhythm, but rather between rheumatic auricular fibrillation and all other kinds of heart failure irrespective of rhythm. The course of the disease after the onset of failure in normal rhythm is short—18 of 29 patients died within a year'. Failure with normal rhythm is relatively more common in India in that for one thing cardiac rheumatism which accounts for about half the cases of auricular fibrillation in Great Britain and Ireland is correspondingly less prevalent in India.

RIGHT-SIDED (CONGESTIVE) HEART FAILURE

This is most frequently a proclamation of previous left-sided failure due to hypertension, coronary disease or aortic valvular disease. But the causal example *par excellence* of right ventricular strain and failure is the correspondingly infrequent congenital condition, namely pulmonary stenosis, which incidentally produces pulmonary ischæmia and a proclivity to pulmonary tuberculosis—the converse effects of mitral stenosis.

The middle share of responsibility for right-sided heart failure is claimed, firstly, by the pulmonary hypertension that is most emphatically produced by mitral stenosis, and, secondly, by pulmonary disease, notably emphysema, both of which quite obviously obstruct the blood flow through the lesser circulation. The ultimate determinant, however, of right-sided failure is coincident right ventricular disease, e.g., arteriosclerosis, which so conspicuously involves the left ventricle, and expectedly implicates the right ventricle as well.

A most exceptional cause of right heart failure, i.e., primary endarteritis of the pulmonary arteries, is nevertheless worthy of recall on this occasion because Sir Leonard Rogers of this College described some cases in Bengal soon after its original description by Ayerza of Buenos Ayres.

The clinical picture of right-sided heart failure is reflected in the venous reservoir formed by the systemic and portal venous systems behind the failing right ventricle. Its main features are, accordingly, engorged cervical veins (Lancisi's sign), engorgement of the liver, and systemic œdema. Dyspnoea is an almost invariable symptom in right-sided failure owing to the fact

that the causes of right-sided failure essentially implicate the pulmonary circuit in the manner indicated above. For the same reason cyanosis is rather more conspicuous here than in left-sided failure.

In pneumonia the right ventricle has to operate against the pulmonary lesion, nevertheless the clinical picture of right-sided heart failure is rarely evident because failure is predominately peripheral. We have already referred to the antagonism existing between shock and congestive cardiac failure in coronary thrombosis, evidently peripheral failure nearly always prevails in pneumonia.

MIXED FAILURE

Mixed failure is usually seen in auricular fibrillation. Both ventricles fail more or less simultaneously from stress of excessive and ineffective beating.

SYMPTOMATOLOGY

'In diagnosis one physical sign is worth many symptoms.'—Horder. I am not sure that this generalization holds for heart disease, in that, for example, a history of effort angina or of a previous coronary thrombosis without abnormal signs, or a history of nocturnal cardiac asthma are all of the highest diagnostic value.

The best method, to my mind, of clinically investigating the ordinary heart case is probably as follows :—

1. The first point is to have in mind what are the symptoms of cardiac damage and decide if the patient has them, ignoring unessential symptoms, *e.g.*, has the patient angina of effort, dyspnoea of effort, cardiac asthma? Incidentally the three most outstanding symptoms of cardiovascular dysfunction, according to standard authors, are dyspnoea, pain, and palpitation. Students call them the 3 Ps—panting, pain and palpitation.

2. The next consideration is, What are the signs of heart disease and has the patient got them? *e.g.*—

valvular disease,
cardiac enlargement,
hypertension,
dilatation of the aorta,
congestive failure,
auricular fibrillation or flutter, and
abnormal electrocardiograms.

DYSPNOEA

The term dyspnoea means laboured breathing registering on consciousness the difficulty experienced by the heart and lungs in meeting their liabilities. Cardiac dyspnoea may be clinically divided into—

1. Dyspnoea on exertion.
2. Dyspnoea at rest—
 - (1) Orthopnoea,
 - (2) Cardiac asthma and acute pulmonary oedema.

Excepting in pulmonary heart disease and in hypertensive heart failure, the respiratory rate in cardiac dyspnoea rarely exceeds 30 per minute. As Christian said 'dyspnoea is poorly, sometimes not at all, depicted by the charted rate of respiration'. When you encounter rapid shallow respiration, you should look for evidence of acute pulmonary or pleural disease, or interpret neurocirculatory asthenia; such polypnoea is usually absent in cardiac disease excepting when the pericardium is involved.

Another remarkable respiratory symptom of neurocirculatory asthenia is sighing or suspirous respiration. Now sighing respiration is a subjective feeling of difficulty in taking a full breath. This is eventually overcome and a deep breath is taken, followed by a long sighing expiration and relief. Sighing respiration often masquerades as 'shortness of breath', 'breathlessness', 'difficult breathing at times', or 'a feeling of suffocation'. Gallavardin's *le trépid*, palpitation, left inframammary pain and sighing respiration is diagnostic of neurocirculatory asthenia. This triad of symptoms is a pleasing contrast to the evil trilogy of left ventricular failure.

Cardiac asthma is a severe grade of paroxysmal dyspnoea due to sudden or acute failure of the left ventricle. Its basis is most frequently hypertensive and arteriosclerotic heart disease, commonplaces amongst the leisured classes of Indians. The tempo of life and the diet of the Indian ryot, on the other hand, are certainly less conducive to such developments. Bronchial asthma and cardiac asthma are frequently confused and so I have tabulated their differential diagnosis.

Bronchial asthma

Cardiac asthma

- | | |
|---|--|
| <ol style="list-style-type: none"> 1. The majority of cases of true spasmodic asthma begin before the age of 25. 2. There is a history of years of sensitiveness to foreign proteins and of respiratory infections, <i>e.g.</i>, winter cough. 3. Wheezing is invariably. 4. The dyspnoea of bronchial asthma is mainly expiratory. | <ol style="list-style-type: none"> 1. Cardiac asthma is very rare before the age of 40. 2. The history of attacks of cardiac asthma rarely exceeds 2 years: I am constantly having patients sent up as cardiac asthma when they have had attacks for 5 to 10 years, which, of course, excludes it. Duration is therefore an important differential point. 3. There may be no wheezing, simply dyspnoea and oedema of the lung bases. Often this oedema affects the small tubes thereby producing some spasm. 4. The dyspnoea of cardiac asthma is both inspiratory and expiratory. |
|---|--|

Bronchial asthma

5. Rhonchi are mainly expiratory, widespread and especially well heard bilaterally over the front of the chest. No moist râles can be detected at the bases behind. Bronchial asthma is characterized by bronchial spasm without œdema of the lungs.

6. Signs of heart disease are absent in uncomplicated bronchial asthma.

7. Bronchial asthma is unlikely to lead to right-sided failure.

8. Bronchial asthma implies a good prognosis and very many years of useful life.

9. Rapid and favourable to adrenalin.

Cardiac asthma

5. Râles are moist inspiratory and basal. Quite frequently they are the squeaky râles of the emphysematous asthmatic subject. In fact the lung signs in cardiac asthma may be indistinguishable from those of bronchial asthma. In cardiac asthma there is œdema with or without spasm: if with spasm the smaller tubes are involved.

6. Signs of heart disease are invariably present in cardiac asthma—

- (1) Hypertension.
- (2) Cardiac enlargement.
- (3) Markedly accentuated pulmonic second sound.
- (4) Gallop rhythm.
- (5) Pulsus alternans.
- (6) Abnormal electrocardiograms especially T₁ negativity.

Confusing factors are—

- (1) The heart rate may be only slightly accelerated.
- (2) The heart rhythm remains normal.
- (3) Heart murmurs are usually absent, though sometimes aortic valvular murmurs or the murmur of mitral stenosis is heard.
- (4) The lung signs may almost entirely mask the heart sounds and any existing murmurs.

7. Cardiac asthma is likely to lead to congestive (right ventricular) failure before long.

8. Cardiac asthma implies a bad prognosis: such patients rarely live 2 years.

9. Responds to morphine and atropine.

PAIN

The coronary, or third circulation, may be conveniently studied by the Harvey film which shows the exposed heart beating. In ventricular systole the musculature and subsequently the coronary arteries are tightly contracted producing thereby a notable pallor of the ventricular walls in testimony to their relatively bloodless state. In ventricular diastole the musculature and subsequently the coronaries relax and the walls become flushed with blood, clearly indicating that the rate of the coronary circulation is optimal in those whose coronary trunks are most highly elastic. Coronary insufficiency productive of myocardial ischæmia results in cardiac pain.

The causal factors, therefore, of cardiac pain are coronary arterio-sclerosis which narrows, and coronary thrombosis which occludes the lumen of the coronaries, and syphilitic aortitis which obstructs the coronary orifices. The low diastolic pressure of aortic regurgitation or the low cardiac output in aortic stenosis may likewise cause cardiac pain as a result of the delivery of an inadequate volume of blood to the coronary circulation and myocardial fibres.

Marked left ventricular enlargement by increasing the territory of the coronary circuit, imposes a further liability resulting in the easier provocation of pain in the subjects of hypertensive heart disease or aortic regurgitation. Cardiac pain is elicited on exertion or excitement because the total coronary diastole per minute is thereby shortened and because coronary sclerosis by limiting the extent of coronary dilatation prevents the coronaries from rising to the occasion.

It is rather interesting to recall that, although Heberden gave a classical description of angina pectoris (paroxysmal substernal oppression) about 1768, it was his friend William Jenner who evolved the essential pathologic lesion, namely, coronary sclerosis. As Jenner's master, however, the great John Hunter, was at the time a victim of angina, his faithful pupil did not disclose his pathologic discovery until after Hunter's death some twenty years later, lest the announcement might prejudice Hunter's career. Jenner predicted and found extensive coronary sclerosis in his necropsy of John Hunter. Thereafter coronary disease was regarded as a pathological curiosity and occlusion was considered to be quite incompatible with life, until Herriek's clinical description of coronary thrombosis (prolonged substernal oppression) in 1912.

PALPITATION

'Palpitation (from the Latin, *palpitare* to throb) is the consciousness of the heart's action, whether fast or slow, regular or irregular. It is generally a disagreeable sensation and sometimes in a sensitive person it is very distressing.'—White.

Palpitation was described and attributed to cardiac dysfunction by Galen, centuries before cardiac pain or cardiac dyspnoea were recognized. It is, however, the least important of the three main symptoms of cardio-vascular dysfunction. The majority of people who complain of palpitation alone have no organic heart disease. When palpitation is associated with heart disease, cardiac dyspnoea and pain are present as well. When palpitation is symptomatic of neuro-circulatory asthenia it is the leading component of Gallavardin's *le trépid*. The child very rarely complains of palpitation, but the nervous adult may complain of a variety of sensations, often of wide reference, to be interpreted as palpitation. Associated aerophagy often confirms the suspicion of a neurogenic origin.

Palpitation may be a primary symptom of neurocirculatory asthenia, thyrotoxic heart, or of hypertension, more commonly, or of auricular fibrillation, flutter, or heart block, less commonly. Carefully note the sensations described, and, if palpitation occurs in bouts, enquire into the onset and offset of such attacks. Thus you may obtain a clue as to the nature of any underlying arrhythmia. 'Feeling the heart turning over', 'giving a jump', or 'seeming to stop', suggests extrasystoles. Palpitation which is 'felt at times' should arouse a suspicion of paroxysmal tachycardia, fibrillation, or flutter.

NEUROCIRCULATORY ASTHENIA

When a neurasthenic subject's most outstanding inferiority is instability and an easy fatigability of his neurocirculatory apparatus, conditions of strain are likely to elicit neurocirculatory asthenia, variously designated soldier's heart, D. A. H., effort syndrome or cardiac neurosis.

Neurocirculatory asthenia may be defined as neurasthenia presenting itself with circulatory symptoms and with signs *usually* of an overactive circulation, such as might occur in normal persons on severe physical exertion if fatigue of the skeletal muscles or of the central nervous system did not intervene to prevent such exertion. It is most commonly displayed by young adults, more especially females. It may complicate infection, heart disease, other chronic illnesses and trauma.

Its importance is twofold

1. It is frequently mistaken for cardiac disease; over 200 years ago Senac stressed this difficult distinction between organic heart disease and nervous disorders.

2. It is often superimposed upon cardiac pathology—rheumatic, coronary, hypertensive, or syphilitic heart disease—with consequent enhancement of strain and worsening of the prognosis: the assessment of each factor in such a case is often not a little difficult. Not uncommonly in the presence of mild organic changes the severity of the symptoms is quite disproportionate to the available signs, and so the main burden of them is rightly attributed to attendant neurocirculatory asthenia.

Symptomatology

The general impression left on the physician is the extreme diffuseness of the manifestations: there are so many things that there are too many—Gallavardin. The combination of excitement, exertion and fatigue precipitate the maximum degree of symptoms.

1. The cardinal symptoms are four, namely, palpitation, left mammary or inframammary pain, dyspnoea, and exhaustion.

2. Vaso-vagal and vaso-motor symptoms include faintness, dizziness, flushing, and coldness of hands and feet, which may be somewhat cyanotic.

3. Symptoms expressive of physical and mental exhaustion and anxiety states, *c.g.*, weakness, lassitude, fatigue, irritability and nervousness.

4. Symptoms suggestive of hyperthyroidism; observe the tremor of the outstretched fingers of the cold clammy hands. This tremor and sweating of the hands, feet and axillæ may be indicative of potential hyperthyroidism and the thyroid may occasionally be found a trifle hard on palpation.

Physical type.—The individual endowed with a hyposthenic constitution is the physical type most likely to exhibit neurocirculatory asthenia. The physique of the hyposthenic individual is poor, the chest long and narrow or flat. The heart is central, vertical and pear-shaped with a low-lying diaphragm. The term 'drop heart' expresses the classical configuration of the nervous heart which is likened unto that of a 'hanging drop'. The nervous make-up is correspondingly poor: the individual belongs to the anxious, worrying, highly-strung, jumpy type with exaggerated deep reflexes.

Physical signs.—(1) Peripheral. (2) Central or cardiac.

Peripheral signs.—The rapid Corrigan-like pulse with widened pulse pressure is suggestive of aortic regurgitation. The systolic pressure is moderately elevated from the increased *vis à tergo*, but the diastolic pressure is normal or even subnormal—thereby distinguishing this central hypertension from essential hypertension.

Central or cardiac signs.—(1) Precordial. (2) Auscultatory. These signs superficially resemble the signs of mitral disease.

Precordial signs.—The cardiac impulse is forcible and jerky (forcible impulse implies increased force *plus* quick out-thrust, whereas a heaving impulse implies increased force *plus* a slow deliberate out-thrust). Its wide diffusion due to cardiac overaction on perhaps a thin chest wall further simulates cardiac enlargement. Palpation, however, reveals the maximal impulse within the mid-clavicular line. In the absence of radiology, palpation of the maximal impulse is the only fairly reliable guide as to the position of the left heart border, provided the heart is not displaced. Precordial or substernal tenderness is not uncommonly noted and is to be regarded as a sign of a sensitive chest wall further sensitized by cardiac overaction.

Auscultatory signs.—The first sound is accented or reduplicated. Accentuation and slurring of the apical first sound may produce a bogus 'slight presystolic murmur' just as accentuation of the second sound may sometimes in these cases produce a bogus 'slight aortic diastolic whiff' at the left lower end of the sternum. Temporary gallop rhythm is occasionally present. Cardio-respiratory murmur and basal and apical systolic murmurs are expected findings in a markedly overacting heart and further

contribute to the not infrequent misdiagnosis of heart disease.

DIAGNOSIS

Palpitation.—Palpitation associated with rapid regular heart action suggests neuro-circulatory asthenia. Gallavardin's triad is diagnostic of it as we have already pointed out in connection with sighing respiration which is never a feature of organic heart disease. Premature beats and paroxysms of tachycardia cause the most prominent palpitation in the subjects of neuro-circulatory asthenia. Incidentally overdosage with insulin may also cause tachycardia, palpitation and cardiac overaction.

Pain.—The heartache of neurocirculatory asthenia replaces the headache of ordinary neurasthenia or the abdominal discomfort of nervous dyspepsia. It is a dull and heavy left breast ache or soreness or gnawing pain due to the impact of an overacting heart upon a sensitive chest wall. It may be punctuated by characteristic, transient, short, stabbing pains like pin-pricks or like sword thrusts in severe cases. The patient's aspect, however, is not that of one suffering from pain.

The heartache or left mammary pain of neuro-circulatory asthenia has been inaccurately described as precordial notwithstanding the fact that it extends far outside the precordium. Left inframammary pain, for instance, may be referred to the left scapula and the extension of left supramammary pain into the left arm often misleads the patient or her friends to a misdiagnosis of angina pectoris. Left supramammary pain may also extend to the left side of the neck. Hyperæsthesia is common and persistent in established cases of left mammary pain. Chest-wall tenderness is, as a rule, remarkable by its absence in cases of pain of coronary origin, including that of coronary thrombosis.

The onset and offset of heartache are usually gradual. It may occur at any time especially during fatigue. Effort on the part of the neuro-circulatory asthenic subject is limited by exhaustion and not by pain. If an anginal subject's pain is elicited by emotion or eating, it will always be induced by exertion as well. Finally the heartache of neurocirculatory asthenia may last for weeks or months with intermissions.

Clifford Allbutt has vividly outlined for us the dissimilar clinical pictures of left inframammary pain and of angina pectoris. 'These faintnesses, palpitation, gasping, stiflings, bodily agitations, hyperæsthesias and psychical commotions', he said, 'are so wholly unlike the ruthless grip of angina pectoris as these frantic alarms are unlike its silent passion.'

A differential diagnostic table of left inframammary pain and angina pectoris by Doris Baker is given below. Her investigation of left inframammary pain under the direction of John Parkinson is a model of clinical research in heart disease.

Angina pectoris

1. Commoner in men.
2. Occurs during effort or excitement; effort is limited by pain.
3. Pain in brief paroxysms, onset and offset abrupt; the paramount symptom.
4. Site of pain sternal, or across the chest, supramammary or brachial; spinal distribution C8, D1, 2, 3, also 4.
5. Aspect expresses great pain.
6. Hyperæsthesia none or only following a paroxysm.

Left inframammary pain

1. Far commoner in women.
2. Occurs any time especially during fatigue; effort is limited by exhaustion rather than pain.
3. Pain generally continuous, lasting weeks or months with intermissions, onset and offset gradual, duration indefinite: one of many symptoms.
4. Site of pain left inframammary extension to left scapula, less often supramammary, rarely and slightly left brachial; spinal distribution D5, and 6.
5. No outward aspect of pain.
6. Hyperæsthesia common and persistent, especially in long-standing cases.

Dyspnœa.—The dyspnœa of neurocirculatory asthenia is subjective rather than objective. It gives the impression rather more of a respiratory dysrhythmia than of laboured breathing. It is not remarkably related to exertion but rather to emotional upsets. It is unattended by evident distress or cyanosis such as may document a correspondingly severe grade of cardiac dyspnœa. We have already referred to tachypnœa and sighing respiration, so characteristic of neuro-circulatory asthenia. Cardiac enlargement and the signs of heart failure are conspicuous by their absence. Dyspnœa in a young person in association with an overacting normal-sized heart is commonly symptomatic of neurocirculatory asthenia. Exertional dyspnœa in persons at and above middle life should be thoroughly investigated from the cardiac standpoint: it is, as we have already said, the paramount symptom of left-sided failure.

Weakness.—Patients complaining of asthenia often subconsciously feel that it must somehow be due to heart disease still undiscovered and they not infrequently convey this subtle suggestion to their physician. In actual fact when general weakness is attributable to heart disease the signs of cardiac disease are obvious inasmuch as the cardiac causes of general weakness are heart failure and active endocarditis.

In pronounced neurocirculatory asthenia general weakness is more prominent being now translated into exhaustion. But the most prominent causes of general weakness, exhaustion and prostration are infectious diseases, nutritional disturbances, malignant disease, nervous disorders, etc., and to these the physician should primarily address himself.

Thyrotoxicosis.—Thyrotoxicosis and severe anæmias are also common causes of an

overactive heart. Exclude thyrotoxicosis by the absence of a staring expression, eye signs, thyroidal signs, elevated B.M.R. and loss of weight. In latent thyrotoxic cases eye signs may be absent and the thyroid is not notably enlarged. In thyrotoxic heart disease, the hands are warm and moist and not cold and blue as in neurocirculatory asthenia, the hair is not infrequently prematurely grey and the heart sounds are very loud and 'angry'.

AUSCULTATION

The secret of successful cardiac auscultation is the positive identification of the *first* and *second* heart sounds by a technique of the mind, ear and thumb well trained in the synchronization of hearing and touch. Apply your chest-piece to the mitral area over the maximal impulse and your thumb to the carotid artery. Shut your eyes as an aid to dissociating everything else from your mind and feel the carotid impact against your thumb coincident with the single intense demarcated auditory impression of the first heart sound. Employ this method deliberately in the auscultation of every heart, rather than spasmodically invoke it in times of auscultatory stress. Thus only can be attained a calm and sure efficiency in disentangling the more complex sounds and murmurs. Evan Bedford and Parkinson invariably employ this technique and so we might with advantage do likewise. Remember that systole equals the first sound *plus* the short pause and that diastole equals the second sound *plus* the long pause. Observe that the first sound is lower-pitched, longer and louder than the second sound, that it is preceded by the long pause and that it is followed by the short pause which separates it from the second sound. Trace the first and second sounds down from the pulmonary area to the cardiac impulse.

Gallop rhythm is such a striking, facile and important auscultatory sign that I cannot refrain from making some reference to it. In gallop rhythm a third or extra sound is introduced into the cardiac cycle. Gallop rhythm, therefore, consists of the usual first and second sounds *plus* an extra sound which is sometimes not only audible but palpable as well. I may discuss the origins of this extra sound in a later paper. However it may be, gallop rhythm must be clearly distinguished from reduplication of the heart sounds which is a partial idea. The three sounds of a gallop are fairly equidistant. In presystolic gallop rhythm the extra sound occurs somewhat before the first sound and the spacing of the sounds is more even than in protodiastolic gallop rhythm where the extra sound occurs immediately after the second sound. The punctum maximum of gallop rhythm is usually about the impulse, though it is frequently audible over a much wider area. Its resemblance to the foot-falls of a galloping horse is best appreciated when the heart rate surpasses 80 per minute. Temporary gallop

rhythm commonly signifies an overacting heart or a severe anaemia or acute myocarditis in diphtheria, scarlatina, rheumatic fever or typhoid fever. Persistent gallop rhythm usually proclaims failure of the hypertensive or arteriosclerotic heart, or it may be a sign of coronary thrombosis or of a bundle branch block, etc. With the abolition of failure the gallop disappears for the time being. The prognostic significance of persistent gallop rhythm is obviously bad. The advent of gallop rhythm may sometimes be foretold at an earlier phase by impurity of the first sound, *i.e.*, prolongation with a tendency to splitting.

THE ESTIMATION OF BLOOD PRESSURE

This is one of the commonest and for all that one of the most important of all clinical procedures. Nevertheless many doctors are rather nebulous about its most vital determination, namely, the diastolic pressure. Obviously the first essential in the estimation of blood pressure is an accurate conception of the whereabouts of the standard systolic and diastolic pressure levels. These are as follows: The systolic pressure is the point where the first distinct sound is heard during decompression and *the diastolic pressure is the point where the loud clear sounds abruptly drop in intensity and suddenly become dull and muffled, or abruptly disappear*. The upper normal blood pressure limits are 160 systolic and 100 diastolic. The blood pressure rises only $\frac{1}{2}$ mm. for each year of life: otherwise stated, age has by no means the importance that was formerly attached to it.

The standard levels are of such primary importance that I do not propose to say much more about the estimation of blood pressure beyond indicating a few cardinal points in technique:—

(1) Apply the cuff on the *inside* of the arm in order to compress the artery against the bone: its application on the outside of the arm is an abortive attempt to bend the bone towards the artery.

(2) So apply the cuff that its lower end lies *immediately* above the bend of the elbow, thus the Korotkow sounds are best heard.

(3) Quickly inflate the armlet to obviate congestion of the arm: slow inflation occludes the veins before the arteries, hence blood continues to enter the limb but is unable to escape with resultant congestion of the arm.

(4) Inflate the armlet to a pressure of 200 mm. lest you miss the silent gap.

(5) Decompress gradually and *at a uniform rate*.

(6) Take at least three to four or more readings until you obtain two concordant readings: the initial reading in nervous subjects is unduly high as compression of the arm is liable to lead to reflex vaso-motor spasm of the brachial artery.

(7) In young hypertensives especially, exclude coarctation of the aorta by palpation of the femoral arteries.

At this year's session of the American Heart Association, Stroud advised the routine taking of blood pressure in both arms. 'For the past eight years', he said, 'I have been taking the blood pressure in both arms of all patients that have come to me, and I can confirm the impression that has been given by this last paper, namely, that there is quite a marked difference in the blood pressure in the two arms in a vast majority of cases.'

The main reason I have taken the blood pressure in both arms is that eight years ago, before the insurance companies had stopped granting total disability insurance, one of Walter Cramp's "all American" football players took out a life insurance containing a total disability clause. His blood pressure was taken by the doctors in the left arm only. His was a \$250,000 policy taken up by three or four companies. This individual had a blood pressure of 120/80 in the left arm. Three weeks after he took out this policy, a cardiac infarct developed while he was playing golf. I saw him six weeks after this infarct occurred, and at that time he had a blood pressure of 120/80 in the left arm, but a pressure of 200/110 in the right arm. Presumably then, if these companies doctors had taken the pressure in both arms, this gentleman would not have been living in Santa Barbara for the last eight years on his income from his total disability insurance'.

Dr. Stroud's advice is a counsel of perfection to the busy general practitioner who may be not unjustifiably content with an accurate reading in one arm.

RADIOGRAPHY OF THE HEART AND AORTA

The modern routine examination of a heart case includes clinical, electrocardiographic and radiological investigations. In Indian medical centres electrocardiography is a rightly established procedure. Cardiovascular radiology, however, has not yet come into its own, probably because the profession is not quite aware of the fact that precordial percussion has been almost entirely abandoned at home on the grounds that it is a demonstrably unreliable procedure excepting in that it may reveal pulmonary emphysema or pericardial effusion. The traditional clinical methods of estimating cardiac enlargement by percussion of the heart fell into complete disuse about 1936 when John Parkinson's radio-cardiological studies disclosed the gross inaccuracies inherent in this time-honoured procedure. In the first Lumleian lecture for 1936 John Parkinson made some trenchant remarks on the percussion method of studying cardiac enlargement. 'The inaccuracy of percussion', he said, 'is inseparable from a method which is indirect and inferential: and this is now generally admitted. No longer shall we tell of the professor who by knocking at the front door could find out who was in the drawing-room. As a final effort to resuscitate a dying

PELLAGRA

By L. EVERARD NAPIER, M.R.C.P. (Lond.)
Professor of Tropical Medicine
Calcutta School of Tropical Medicine

INTRODUCTION

THIS note was prepared in order to draw attention to this disease. If medical officers in India were more familiar with the signs and symptoms of pellagra, it is probable that far more cases would be diagnosed; I am therefore giving a short description of the disease as it is usually encountered*.

HISTORICAL

Pellagra is a disease with a considerable historical background. It was mentioned first in the seventeenth century as occurring in Spain and in 1735 it was described accurately by Gasper Casal.

His book was not, however, published until 1762. Figure 1 is a reproduction from this book (Major, 1932). Meanwhile M. Thiéry described the disease in the *Journal de Médecine, Chirurgie et Pharmacie* (Paris, 1755) acknowledging his debt to Casal.

*This note is followed by two clinical reports, one on the findings in the five cases that were admitted to and treated in our hospital recently and the other a report on pellagra in the Kangra valley by another writer.

(Continued from previous column)

method which is packed with fallacies and imperfections, there have been attempts to square the results of percussion with those of radiology, but they have led to nothing. The best proof that it (cardiac percussion) is to be extruded from our important and growing number of clinical and laboratory methods is the fact that it is sterile. The tokens of sterility are upon it. Nothing has been added to medical knowledge or progress through cardiac percussion since the beginning of this century, and in the light of x-rays it will shrink into obsolescence'. It has, 'x-rays', he continues, 'tells us literally everything that percussion can tell us and tell it more amply and precisely'. 'More faithful witnesses are eyes than ears'.

I acknowledge my great indebtedness to the writings of British, American, Continental and other cardiologists past and present. My gratitude to my teachers, more especially to Dr. Evan Bedford, is certainly not less. In conclusion I would strongly advise those who wish to keep abreast of the times in the matter of clinical heart disease to add to their library the new official mouthpiece of the Cardiac Society of Great Britain and Ireland, the *British Heart Journal*. 'As the calorimeter tells the activity of the patient's metabolism, so you may determine the plus or minus activity of the local profession in any district by the condition of its library'.—Harvey Cushing.

The following is an extract from this description :—

Description of a Malady called mal de la Rosa

Among a large number of complications which accompany this disease, there is one which characterizes it and makes it very easy to distinguish. This is a horrible crust, dry, scabby, blackish, crossed with cracks, which causes much pain to the sufferer and throws off a very fetid odour. This crust may be upon the elbows, the arms, the head, the abdomen, etc. But the people of Asturias, where this disease is endemic, do not give it the name of *mal de la Rosa* unless it is located exactly on the metacarpals or metatarsals of the hands or of the feet; and following them in this restriction I am going to write in a few words the history of this disease.

It commences ordinarily towards the spring equinox, more rarely at other seasons. In the beginning it is nothing more than a simple redness accompanied by roughness. It degenerates later into true crusts such as we are going to describe. They dry up ordinarily during the summer, and the affected metacarpus or metatarsus is completely rid of its crusts or pustules. There remain red and shiny marks, very smooth, and denuded of hair, more sunken than the neighbouring skin, resembling somewhat those scars which burns leave after they are cured. It is probably the red and glossy colour of these marks which has given to this disease the name of *mal de la Rosa*. These scars, besides, in those who have been affected for a long time with this kind of illness, last their entire life; and every year at spring time they become re-covered with new crusts which become more horrible from year to year. They do not always involve the two hands; sometimes one sees them on one hand alone and on one foot; sometimes on two hands and on one foot. It happens also that they involve all at once both hands and both feet. They do not extend to the palms of the hands or the soles of the feet; they involve constantly the back, either extending thus over the entire metacarpals or metatarsals, or they cover only a slight portion.

There is another very remarkable sign of this disease, which, in truth, is not essential to it, because it is not always present; but, as it is never observed in other diseases except this one of which we speak, we may regard it as an accompaniment. This symptom is another crust of an ashy and jaundiced colour, which involves the anterior and inferior portions of the neck, extending out from here and along the clavicles and the superior extremity of the sternum, forming a band as wide as two fingers. It rarely covers the entire back of the neck; most often the middle portion of the trapezius muscle remains free, and prevents this collar from making a circuit of the neck, but, in revenge, it forms ordinarily on the sternum a lesion of the same kind and the same size which extends the length of this bone to the middle of the thorax. This malady does resemble the collar of an order, which renders the Asturian, thus unfortunately affected, very easy to distinguish from all of his fellow citizens.

So singular a disease ought to be without doubt accompanied by peculiar symptoms. Independent of the horrible crusts of which we have just spoken, the patients are attacked by a perpetual shaking of the head and indeed of all the upper part of trunk. This trembling is often so marked that they can scarcely keep on their feet. We have seen a woman in the hospital whose head and trunk trembled so as to resemble a reed continually shaken by the wind. She could not hold herself upright without changing every moment the position of her feet, holding thus by instinct the equilibrium which this perpetual trembling caused her to lose. The patients have further a painful burning of the mouth, vesicles upon the lips and they have a dirty tongue. They complain of extreme feebleness of the stomach and of all of the body, principally the thighs, and of a heaviness which takes away from them all activity. At night they feel a

burning which often deprives them of slumber. The bed is then insupportable to them because of the heat, but they do not feel better with cold; the slightest degree of cold or of heat is equally insupportable to them. They are sad and melancholy: one sees them shedding tears and emitting cries without any object, although otherwise they seem to possess their reason. They claim that they are compelled to in spite of themselves by the nature of their illness. These symptoms besides are common to all. And here are a few of them in detail. Slight delirium, a certain stupidity, loss of certain senses, of taste and of touch principally, crusts, ulcers, erysipelas in different parts, irregular fevers, restless slumber, the skin entirely discoloured, and elephantiasis to a slight degree.

This disease is terminated most commonly by hydrops, by lymphatic or scrofulous tumours, and by marasmus. It has also another termination but it does

Fig. 1.—Patient suffering from *mal de la Rosa* (pellagra).
From Casal's *Memorias de Historia Natural de Asturias* (1762).

not happen indifferently at every season. This is the mania into which these unhappy sufferers fall towards the summer solstice. This mania is not ordinarily severe but however it deranges the mind of the patients and forces them to leave their dwellings and to save themselves in solitude where the excess of *ennui* and of illness throws them sometimes into great depression. It should be remarked that this maniacal melancholia which follows at the height of summer in those who are affected by the *mal de la Rosa* are much more terrible, and more commonly mortal than those of which have another origin. Without doubt because these are produced by metastasis to the brain of the acrid and malign humour which produced this malady. But what is its nature? If one wishes to describe with care the symptoms which we have described one would not be far from thinking that it is a mixture of leprosy, tetter and of scurvy which constitutes a disease of a peculiar and definite type which has its proper and constant symptoms. This malady has never been described as far as I know, and does not exist perhaps

elsewhere with as much violence as in Asturias, especially those of Oviedo: for the Asturias of Santillana are more healthy by the nature of the soil, by the quality of the air, and of the food. . . .

* * *

M. Casal, physician of the Court, who adds to a taste for observation all the frankness of the earlier times, who has practised medicine in Asturias for 25 or 30 years and from whom I take the history which I have just read; this wise observer, I say, assures me that the *mal de la Rosa* has always resisted all remedies, and that he regards it as incurable. Moreover he cites the example of a woman of the people who, during one of the melancholy deliriums so frequent in this disease,

Fig. 2.—Patient showing pellagrous dermatitis on extensor surfaces of arms and forearms, on the backs of the hands, and on the dorsa of the feet.

had a great desire to feed herself from cow's butter, for which she spent all of her property, and she was cured.

In 1776, pellagra assumed serious proportions in Italy and legislative action was taken to control the sale of maize on this account. A century later Lombroso, an Italian worker, again incriminated maize as the cause of the disease, but suggested that it was due to a special maize toxin developed during storage and as a result of action taken by the local authorities by 1900 the disease incidence in that country had fallen from 4,000 to 100 deaths per annum.

Attention was first drawn to it in America in 1907 and in 1916 as many as 150,000 cases with 15,000 deaths were reported in the United States.

Cases have been reported in England, where it is an institutional disease and in southern Europe, Egypt, South America, and elsewhere.

In India, the first series of cases was reported by Lowe (1931) who had found about 40 cases amongst the inmates of Dichpali Leper Hospital, Hyderabad, Deccan. Isolated cases have been reported from time to time from different parts of India and it seems probable that the condition is widespread in this country although it apparently never assumes epidemic proportions.

EPIDEMIOLOGY

Pellagra is seen in its most characteristic form in poor populations whose staple diet is maize. It does also occur in countries where maize is not the staple diet, and sporadically amongst people who do not include maize or maize flour at all in their dietary. However, when it occurs amongst the latter class the diet is nearly always found to be poor, monotonous, and of low protein and vitamin content.

In more prosperous countries it occurs mainly in institutions and in prison camps where the food is scarce and deficient in variety. It very rarely occurs amongst people on a good mixed diet, but it has been reported in patients who have been placed on a restricted diet for medical reasons and who have continued this diet for long periods without reference to their medical advisers.

Finally, it has been reported amongst alcoholics; the ætiology in this case is not clear, but it is probably associated again with a low dietary intake—common amongst alcoholics—or to a lowered absorption through the associated gastritis.

The disease shows a definite seasonal incidence, though the season is different in different countries, it is constant in any one country. In cool countries it occurs in the summer and autumn, and in hot countries in the cooler months of the year. The explanation of this apparent anomaly is that sunlight plays an important part in the ætiology; in the former countries there is more sunlight in the summer months, and in the latter people tend to avoid the sunlight in the hottest months whilst exposing themselves in cooler months. It is noticed that people susceptible to the disease suffer from an exacerbation of symptoms at the same time each year, but that in a pellagra-endemic area there are 'bad' years and 'good' years.

It is far more common amongst outdoor workers, agricultural labourers in particular. Hard work is a contributing ætiological factor. Generally, therefore, the disease is more common amongst men, but in India it appears to be more common amongst women.

It occurs at all ages, from three months to a hundred years.

ÆTIOLOGY

The exact ætiology is not yet understood fully, but during the last few years much has been done on the subject, and many definite facts

have been established. The current theories regarding the aetiology can be classified as follows :—

The maize infection theory.—It has been suggested that in certain cases maize is, or after defective storing in damp conditions becomes, infected and produces the disease in those who consume it, directly, or indirectly by interfering with absorption or by causing decomposition. Though the disease appears in epidemic form amongst maize eaters and legislative measures aimed at controlling and improving the storage of maize have apparently reduced the incidence in the past, the disease is never transmitted to people on a good diet, and there is little, if any, experimental support for this theory.

The maize toxin theory.—The neurological changes that occur appear to be of toxic rather than bacterial origin, and support has recently been given to this theory by the occurrence of pellagra amongst individuals taking maize alcohol, but there is no evidence, experimental or otherwise, to indicate the actual nature of this toxin and attempts to isolate it have failed. Further, many people who have never taken maize in their diet suffer from pellagra.

The constancy of the skin lesions and the fact that the general symptoms run parallel to these, improving in the cold and sunless months of the year, for example, has led to the suggestion that a pre-toxin is ingested or formed which is converted into a toxin by the action of the ultra-violet rays.

But Stannus (1937) and Sebrell (1938) are of the opinion that the effect of the sun is purely a matter of trauma, and that the skin in its ill-nourished state is particularly liable to damage, or, to put it another way, the fullest effect of the morbid changes due to pellagra will fall on tissues already damaged by ultra-violet radiation from the sun, by infra-red radiation from a fire, or by friction of the clothes.

Protein deficiency.—This theory is dependent on the fact that all pellagra-producing diets are low in protein content. Maize has a very low protein content compared with other cereals (see table, column 2), and, further, the biological value of the protein is also very low (see table, column 3). The two facts combined make maize a very poor source of good protein (see table, column 4).

Specific protein or amino-acid deficiency.—Maize is defective in protein, quantitatively, qualitatively, and in the variety of protein substance present; there are, for example, certain important amino-acids absent in a pure maize diet, e.g., tryptophane and lysine. It is suggested that some such specific deficiency is the cause of pellagra.

Vitamin deficiency: absence of the PP (pellagra preventing) factor from the diet.—

The PP factor is part of the vitamin-B₂ complex which contains, amongst other things, nicotinic acid, lacto-flavine or riboflavine, and B₆ [anti-dermatitis (rat) factor]. Diets that are

rich in vitamin B₂, such as yeast, meat, and liver extract, rapidly cure uncomplicated pellagra, even in patients who are left on their otherwise pellagra-producing diet.

TABLE

	Percentage protein content *	Relative biological value of the protein *	Relative biological protein value per given weight of substance
Beef ..	22.7	98	100.0
Wheat ..	11.7	67	35.2
Rice ..	8.5	80	30.5
Milk † ..	3.3	85	12.6
Maize ..	4.3	60	11.6

* From Aykroyd (1937).

† The low position of milk, a substance of high nutritive value, is because it is a fluid substance (87 per cent moisture) being compared with solids.

For this theory strong support has been obtained from animal experiment. Dogs fed on

Fig. 3.—Typical pellagrous lesion on the backs of the hands.

a pellagra-producing diet develop a condition known as 'black tongue', which clears up rapidly when vitamin-B₂ complex is added to the diet.

Recent work, which will be referred to in greater detail under treatment, has shown that nicotinic acid is the fraction of vitamin-B₂ complex that is specific in pellagra, as far as the skin and mucous membrane lesions are concerned, but that unless vitamin B₁ is also given there is no improvement in the peripheral neuritis.

It has been shown that the dermatitis which is produced in rats and has been named 'rat

pellagra' also does not respond to nicotinic acid, but improves when vitamin B₆ is given, an observation which proves that this condition is not analogous to human pellagra.

The present tendency is to consider that nicotinic acid is the PP factor, and further that clinical signs and symptoms which do not respond to adequate doses of this substance are not part of the true pellagra clinical picture, but due to associated deficiencies.

There is just one other possibility that should be considered, namely, that there is a toxic factor present in maize and to a less extent in other food substances, which is neutralized by nicotinic acid and by other associated dietary substances, so that it only exerts its influence when

Fig. 4.—Pellagrous lesions on forearms and hands.

these are absent or deficient; in other words, that there is a state of 'conditioned toxicity'.

PATHOLOGY

The skin.—The changes are primarily inflammatory and then atrophic. There is parakeratosis of the epithelial layer, increase of pigment in the Malpighian layer followed by œdema and desquamation, which leaves the surface red, pigmented, and rough. The vessels of the dermis show hyaline degenerative changes.

The nervous system.—There are degenerative changes in the peripheral nerves, cord, medulla,

pons, cerebellum and cerebrum. The lesions are by no means constant, and different observers have described them in different systems. The posterior tracts seem to be more frequently attacked than the lateral tracts. Atrophic changes and pigmentation of the anterior horn cells and of the sympathetic ganglia occur. Mott described the picture as a combined sclerosis of the cord. There is demyelination and Wallerian degeneration of the nerve fibres.

Alimentary tract.—The mucous membrane of the whole tract including the tongue and mouth shows hyperæmia and sometimes ulceration: this is followed by atrophic changes in the mucosa and also wasting of the muscular coat.

Other organs.—There is wasting and brown degeneration of the heart muscle. There is fatty degeneration of the liver and kidneys, and atrophy and focal necrosis of the spleen. The supra-renals show atrophic changes in both cortex and medulla and occasionally hæmorrhages.

Blood picture.—Anæmia is the rule: it is said to be usually of the microcytic type and to be associated with leucopenia.

Biochemical findings.—There is a marked increase in coproporphyrin in the urine which disappears when successful treatment is given.

There is usually achlorhydria or marked hypochlorhydria; but Castle's intrinsic factor is present in the secretions (there is at least no evidence of its absence in the blood picture).

SYMPTOMATOLOGY

The onset may be either with dermatitis or gastro-intestinal symptoms, but in other cases pain and difficulty in swallowing hot or spicy foods are the first symptoms noted; the case histories in any particular group of cases are usually similar. There are periods of improvement and then of relapse, and it is usually noted that both the onset and the periods of exacerbation occur at the same season of the year.

Dermatitis.—The skin lesions, which are usually symmetrical, suggest sunburn at first but the hyperæmia does not clear up; then large scales form which may separate and leave a red pigmented rough area.

The distribution of the skin lesions is typical: in 77 per cent of cases they appear on the backs of the hands: other common areas are on the extensor surfaces of the forearms and arms, on the dorsa of the feet (where these are exposed to the sunlight), on the shoulders, on the back of the neck, and on the malar eminences; these are the areas that are most affected by sunburn. Other sites are the genitals and axillary folds, especially when these areas are subjected to pressure of clothing. The facial lesion often takes the form of a symmetrical butterfly rash. Typical lesions are shown in figures 2, 3 and 4.

Intestinal tract.—The attention to the mouth is first attracted by difficulty in taking hot and spicy foods. The tongue is œdematous; at first

red and swollen, it then loses its epithelium and takes on the characteristic glazed appearance: there is a general inflammatory condition of the whole tongue and mouth, with aphthous ulcers along the edge and on the frenum of the tongue. There is increased salivation. The pharynx becomes involved in the same process. This leads to difficulty in swallowing and disinclination to take food soon follows.

Later, the tongue may become completely denuded of epithelium, atrophied and fissured.

The bowel symptoms are not by any means constant, but there is often a troublesome diarrhoea of the enteric type. There is usually discomfort in the upper abdominal segment after food and later a persistent burning pain is complained of: there is evidence of gastritis which is associated with specific malnutrition of the mucous membranes generally, and is in keeping with the constant hypo- or achlorhydria.

General and nervous.—Tremors of the tongue and face muscles are noted early in the disease, Chvostek's sign (a spasm of the facial muscles on tapping) has been noted; later, this extends to other muscles; there are fleeting pains in different parts of the body, numbness and paraesthesias; the reflexes are exaggerated in some cases and there is a spastic rigidity, but in others they are lost. Peripheral neuritis is often very troublesome, but recent work tends to suggest that this is an associated condition.

Later, mental changes are a characteristic symptom of the disease: there is dullness, headaches, confused thought, insomnia, depression amounting to melancholia which often leads to suicide. In some cases a manic-depressive syndrome has followed periods of excitement with hallucinations.

Other signs and symptoms.—There is often irregular fever, but it is not a constant symptom nor is it probably associated with the central pathological and symptomatic syndrome. Anaemia is usually noted: this has been mentioned above.

Prognosis.—This will naturally vary with the circumstances. If the patient, even in an advanced stage, can be placed under ideal hygienic and dietetic conditions treatment is usually easy and in most cases will end in complete cure, but there may be a relapse when the patient returns to his previous mode of life. The disease, however, usually occurs amongst poor populations where the intensity of the symptoms will vary according to the degree of the dietary deficiency, and the usual history is that of improvement during the cold months of the year (in sub-tropical climates) with progressive relapses during the summer months.

The death rate in Italy is given as 3 to 5 per cent, but in some outbreaks in America it has been placed as high as 30 per cent.

In alcoholics and in chronic malarial and dysenteric subjects the prognosis is bad.

Diagnosis and differential diagnosis.—There are no specific laboratory tests, but the increase of porphyrin in the urine when it occurs is suggestive and recent work suggests that response to nicotinic acid constitutes a specific therapeutic test. Otherwise the diagnosis depends on the history of the locality and diet, the chronicity and seasonal variations, and the characteristic clinical syndrome. The semi-popular diagram, adapted from Gregory (1938), may be of some help for memorizing the outstanding points, but in it no account is taken of the stomatitis.

It has to be differentiated from sprue (more constant macrocytic blood picture, less constant achlorhydria, and fatty stools), other dermatitis (simple solar, trade, and syphilitic), lupus

Fig. 5.

erythematous, tabes and general paralysis, beriberi, ergotism, and lathyrism.

TREATMENT

If the aetiology of pellagra presents any difficulties, the treatment certainly does not, in as far as the treatment of the individual moderately advanced case is concerned. The real difficulty arises in the treatment of large poor populations and here the problem becomes an economic one.

The treatment is dietetic and symptomatic. The patient should be removed from the unsatisfactory surroundings, put to bed in hospital or

under good home nursing conditions, and given a good mixed diet, 20 per cent above his normal caloric requirements, in which there is plenty of milk, meat (if not taboo), eggs, whole wheat meal, vegetables, and fresh fruits. The ration of vitamin-B₂ complex should be augmented by the addition of yeast, as a dry powder or, in cases where yeast is not well tolerated, of liver extract which can be given parenterally when intestinal absorption is poor.

Drugs do not form an essential part of the treatment and in uncomplicated cases complete cure can be effected without them, but sodium thiosulphate 0.5 gramme daily will help the skin condition, arsenic in the form of Fowler's solution is recommended by some writers, and, if there is a microcytic anaemia ferrous sulphate gr. vi. three times a day should be given.

Most of the symptoms will disappear on the administration of a suitable diet, but, if diarrhoea persists, kaolin, bismuth or even opium should be tried in turn, and, if constipation then supervenes, liquid paraffin should be given nightly. The stomatitis should be treated with a mild antiseptic such as borax and glycerine and, if painful to the extent of interfering with the taking of proper nourishment, cocaine may be added to the mouth application, 2 grs. to the ounce. For the mental symptoms and sleeplessness sedatives may be necessary, such as bromides or luminal.

For the peripheral neuritis vitamin-B₁ concentrates are indicated.

Specific treatment.—The diet which has been recommended is rich in the pellagra-preventing (PP) factor. Recent investigations have identified this factor with nicotinic acid which can therefore be given separately by injection or by mouth.

The effect of giving this substance even without altering the diet is dramatic and improvement occurs with amelioration of most of the symptoms and a general sense of well-being within as short a time as twenty-four hours.

The dose recommended by different workers varies considerably, but a good average dose is 500 mgm. daily by mouth for three or four days, though a daily dose up to 1,800 mgm. can be tolerated, followed by 100 mgm. daily as a maintenance dose until all symptoms disappear.

An interesting result of this specific therapy is that it has separated the symptoms that can strictly be included in the pellagra clinical syndrome from the associated symptoms, the most striking example being the peripheral neuritis which does not respond to nicotinic acid and demands the administration of vitamin B₁ (Spies and Aring, 1938). These workers draw attention to the fact that vitamin B₁ is not always absorbed by the stomach and that parenteral injection may be necessary.

It is possible to bring about a cure by nicotinic acid in patients who are still being given a

pellagra-producing diet, but this method is not recommended, as there is an early relapse directly the nicotinic acid is discontinued.

Vilter, Bean and Spies (1938) have pointed out that nearly all pellagrins are suffering from chronic protein deficiency and that complete and lasting cure will not be effected without increasing the protein diet also.

Prophylaxis.—As the disease is a dietetic one, prophylaxis is necessarily an economic rather than a medical problem.

Legislative measures to control the storage and sale of maize have been resorted to in the past in some countries, but are unlikely to be very helpful as there is little evidence nowadays that bad storing of maize is in any way responsible, and it is usually amongst poverty-stricken populations who cannot afford better cereals that maize is used as the staple diet.

In the areas where the disease is endemic, much can be done by education and propaganda. If the people are made to understand the necessity for including certain substances in their diet they will often find the means to provide it. Again, if they are made familiar with the signs and symptoms of the disease and told that these are readily amenable to treatment, they will present themselves for this treatment.

It has been suggested that the introduction of nicotinic acid is an event of economic as well as scientific importance as it provides a comparatively cheap means of supplementing pellagra-producing diets. Schmidt and Sydenstricker (1938), who have tested the prophylactic effect of 100 mgm. of nicotinic acid twice a week, found that this amount did not protect a population on pellagra-producing diet, but Spies *et al.* (1938) reported that daily doses of 50 mgm. would protect some individuals, though larger amounts were sometimes necessary.

Where the question of cost is not paramount, there will be no difficulty in adding substances rich in the PP factor to any diet, non-vegetarian, vegetarian, or even invalid.

R. N. CHAUDHURI, M.B.

and

L. EVERARD NAPIER, M.R.C.P. (Lond.)

Department of Tropical Medicine, Calcutta School of
Tropical Medicine

PELLAGRA is a disease that occurs sporadically in many places in India. At the Calcutta School of Tropical Medicine we see probably 6 to 12 cases a year. The patients usually attend the skin diseases out-door clinic. The following five patients who had been referred to the department of tropical medicine consented to come into hospital for more complete investigation than is possible in the out-door department :—

Pellagra cases

Case 1.—Mrs. R. N. B., Punjabi Hindu female, 36 years old, vegetarian, admitted on 18th January, 1937, for symmetrical dark pigmentation of both upper and lower extremities, gradual weakness—duration six months, amenorrhœa—duration four months, and diarrhœa.

On examination the patient was found to be of thin build; she had pyorrhœa and pharyngitis; her tonsils were healthy, and her tongue clean and normal in appearance. Her temperature was normal and her pulse rate 100 per minute. Her heart was normal in size; the pulmonary second sound was accentuated; the lungs did not show any abnormality; and the liver and the spleen were not enlarged.

The skin of both hands, forearm and the back of the elbows and of both legs and feet showed a dark pigmentation and were very rough.

Laboratory tests

Blood counts.—See table. The Wassermann reaction was positive. The aldehyde and antimony tests and van den Bergh tests were negative, and no malarial parasites or microfilaria were present. The urine showed a trace of albumin, but no casts.

Her stools showed no protozoa, helminthic ova or pathogenic bacteria.

Gastric analysis was done on 4th and 8th February and showed complete achlorhydria, even after injections of histamine, and achylia.

Treatment.—The patient was at first treated for her diarrhœa with astringents and for dermatitis with local applications of Lassar's paste and later liniment of calamine. This had little effect. She was running a low fever. She started severe vomiting on the 29th January and was transferred to the charge of the senior writer. With restrictions of diet and gastric sedatives the vomiting stopped. The patient was next put on marmite 3iii daily and thyroid extract gr. i every morning. After gastric analysis had been done, the patient was put on dilute hydrochloric acid and pepsin mixture; she was kept on this regime for about three weeks.

Progress.—The diarrhœa gradually subsided, the temperature came down to normal and the pigmentation began to clear up within a few days of starting this treatment. Blood examination on 24th February showed hypochromic anæmia, so she was given a course of ferrous sulphate, gr. xviii daily, for three weeks. Her anæmia was cured within a month of starting ferrous sulphate, all patches of dermatitis had disappeared and the patient had gained 8 lb. in weight before she was discharged on the 24th March, 1937.

As the Wassermann reaction was positive and there were bilateral tubo-ovarian masses present, the patient

was instructed to undergo treatment at the out-patients' department for these conditions.

Remarks.—The skin lesions in this patient were typical, but though she was dull and unresponsive it was not possible to say that her mental condition was in any way abnormal. Her blood picture was still microcytic and hypochromic, but her hæmoglobin was up to the normal average of her class at the time of discharge.

Case 2.—D. C., Bengalee Hindu female, aged 35 years, admitted on 2nd June, 1937, for upper and lower extremities : : two months. The dermatitis started as small papules on the toes, spreading upwards, with discharge and exfoliation.

On admission, the patient was anæmic and there was œdema of the legs. There was exfoliation of the skin around the mouth with pigmentation, the teeth and mouth were very unhealthy and the tongue was red and sore. She had low fever and her pulse was 110. Her heart and lungs showed no abnormality, the liver was tender, the descending colon was thickened and tender, and the spleen not palpable. No other abnormality was detected.

Laboratory tests

Urine showed a faint trace of albumin, a few pus cells were present; no casts seen.

Stool.—Cysts of *Giardia* and *Entamoeba nana*; no pathogenic bacteria were isolated on culture, and there were no ova.

Blood.—Wassermann reaction was weakly positive, the van den Bergh test was negative (also see table).

Gastric analysis on 28th June without histamine showed complete achlorhydria; peptic digestion—nil.

On 3rd July after histamine, N/10 HCl = 0, 0, 9, 26, 43, 40, 34, 12, 0 in the consecutive estimations, at fifteen-minute intervals, histamine being given after the second sample had been taken.

Treatment.—The patient was put on marmite 3iii daily, and local treatment (liniment calamine). She was given bitters and alkalies, and dilute hypochloric acid with pepsin later (after gastric analysis had been done) for her gastric condition, and an eight-day course of stavarsol for lamblia infection.

Result.—Stomatitis and diarrhœa disappeared soon after she started taking the acid mixture, and the dermatitis gradually subsided. The patient's general health improved (she gained 16 lb. in weight during her stay in hospital) and her anæmia also improved considerably.

Case 3.—R. D., Sikh female, aged 50 years, vegetarian, was admitted on 14th March, 1938, for (1) symmetrical pigmentation of the hands, arms and legs—duration ten days, and (2) indigestion, flatulence and diarrhœa—duration two months.

On admission the patient showed signs of loss of flesh, the tongue was furred and the teeth were unhealthy (decaying and tartar + +). No abnormality was detected in the heart, lungs, abdomen or nervous system. No history of consumption of maize.

She had immature cataracts in both eyes.

Laboratory tests

Routine examinations of urine and stools showed no abnormality. The Wassermann reaction was negative; the van den Bergh test was negative.

Gastric analysis.—

18th March, 1938—complete achlorhydria and achylia.

23rd April—after histamine—complete achlorhydria.

Blood counts.—See table.

Mantoux test—0.00001 c.cm. ++.

Treatment.—The patient was put on marmite 3vi daily and dilute hydrochloric acid 3ss. with glycerine pepsin 5i, twice daily after food.

Result.—Within ten days the stools became quite normal and the dermatitis was subsiding. The patient's

general health and the blood picture improved very much—she gained 10 lb. in weight and all her symptoms subsided before she was discharged on 26th April.

Case 4.—R. T. J., Nepali Hindu male, aged 55 years, a comparatively well-to-do lawyer, was admitted as a paying patient on 8th April, 1938, for patches of dermatitis in different parts of the body for one year, and soreness of the tongue.

The patient had suffered from asthma for 24 years. He had small patches of dermatitis on both ankles for some years; these appeared and disappeared intermittently during these years. Since March 1937, the dermatitis had spread to his legs, knees, hands and face. He developed a patch on the chin in March 1938 and some patches on the forehead soon after. He had had soreness of the tongue for a long time, but this had increased during the seven weeks preceding his admission into hospital, and he could swallow only liquid food. He gave a history of taking a considerable amount of alcohol.

On admission.—He was found to be slightly anæmic. He had patches of dermatitis on his ankles, knees, thighs and hands, more or less symmetrical in distribution, and there were patches on his chin and forehead. The tongue was denuded of epithelium, red and sore. His lungs showed signs typical of asthma and the heart sounds were muffled by the wheezing ronchi. The liver was palpable and tender. No other abnormality was detected, except in his mental condition which was not normal.

Laboratory tests

Urine—no abnormality.

Stools—no abnormality at first but later, when the patient had an attack of dysentery, macrophages, red blood cells, pus cells and vegetative *E. coli* were present.

Blood.—Microfilaria were present in the blood; van den Bergh indirect was positive, bilirubin = 0.8 units.

Agglutination (when the patient had dysentery) against Flexner-Y + 1/100. Shiga—negative.

The Wassermann reaction was negative.

Blood count.—See table.

Gastric analysis.—

12th April—achlorhydria, no peptic digestion.

22nd April—after histamine. Free HCl = 0, 0, 0, 4, 6, 4, 6, 0 in consecutive samples. Partial peptic digestion.

Treatment.—The patient was put on campolon 2 c.cm. daily for ten days, marmite 5vi daily, local application of liniment of calamine, besides expectorants for his cough. After the gastric analysis, he was put on dilute hydrochloric acid and pepsin.

Result.—The skin condition started to improve within a few days. By the time the campolon injections were finished the mental condition showed very marked improvement. The general health also improved and he gained 6 lb. in two weeks. After this the patient had an attack of influenza and, later, an attack of bacillary dysentery. This reduced his weight by 4 lb., but the skin condition and stomatitis continued to improve and were completely cured before he was discharged on 7th May.

Remarks.—An unusual feature of this case was that he had typical pellagra patches on the inner sides of his knees which puzzled us at first until he improved in health when one morning we found him sitting on his bed with his legs crossed and his thighs abducted and everted, so that the patches would have been fully exposed to the direct rays of the sun had he been sitting in the open. He admitted that this was how he sat most of the day.

The other point was the extremely rapid improvement in all his symptoms, including his mental condition.

Case 5.—B. N. S., a Bengalee Hindu male, aged 35 years, a poor cultivator, non-vegetarian, was admitted on 18th January, 1935, for pigmentation of the skin, soreness of the tongue and ulceration at the angles of the mouth, anæmia and oedema, gradual weakness—duration two years. Abdominal pain and diarrhoea—duration eight days. The patient had had an attack of dysentery two years before.

On admission.—The patient was found to be anæmic. There was some degree of proptosis and the patient had a starved look. The hair and the eyelashes were greyish-white in colour and there were patches of pigmentation on the limbs and over the body. There was excoriation and slight ulceration at the angles of the mouth: the tongue was ulcerated. There was oedema of the legs. His mental condition was dull generally, but he was irritable and obstinate at times. The teeth and gums were unhealthy, his tongue denuded, red and sore, and the pharynx was congested. The lungs showed signs of bronchitis. The heart was slightly enlarged and hæmic murmurs were audible. The liver and the spleen were not palpable. The colon (ascending and descending) was thickened. The knee jerks were exaggerated.

Laboratory tests

Urine and faeces.—No sugar or albumin, and no pathogenic organisms or helminthic ova were present.

TABLE

Case	Date	Hæmoglobin in grammes per 100 c.cm.	Red cells in 10 ⁶ per c.mm.	Reticulo-cytes per cent of red cells	Cell volume per cent	MCV	MCH	MCHC	Leucocytes per c.mm.

	11th May "	9.5	3.44	0.1	31.0	91.2	27.9	31.9	6,600

Blood.—The van den Bergh test was negative. Wassermann reaction was doubtful.

Blood count.—See table.

Sputum.—No acid fast bacilli.

Basal metabolic rate.—plus 38 per cent.

Gastric analysis.—Achlorhydria, even after histamine; peptic digestion—nil.

Treatment.—The patient was put on marmite 5vi daily and dilute hydrochloric acid and pepsin mixture twice daily after meals, in addition to symptomatic treatment for bronchitis and diarrhoea.

Progress.—The oedema persisted though the looseness of the bowels, the dermatitis and sore tongue slowly improved; the amount of urine passed was very small (16 to 20 ounces). Injections of salyrgan were given in order to remove the oedema and promote better flow of urine. This was successful to a great extent.

After a month the blood condition had improved markedly, the pigmentation was much less, and the stomatitis had disappeared. After the second month of treatment, the hair had grown darker and the pellagra dermatitis was present only in one small area on the left leg. The amount of urine passed daily was however very small and salyrgan had to be continued. The patient's blood condition had received a setback, so he was given a course of ferrous sulphate. This led to slight improvement.

The symptoms were gradually relieved with this treatment. The patient suffered from an attack of acute bronchitis and another of phlebitis of the right femoral vein during the next two months. The improvement was very slow and some degree of mental change remained. The patient, however, had always been somewhat abnormal mentally long before he suffered from the present attack.

Summary

Three were women and two were men. None was indigent, but four were from poor families and one was comparatively well-to-do; this last man was an alcoholic.

The only unusual symptom was that one patient's hair was a light brown, almost straw colour; it recovered its natural dark brown colour during treatment.

The incidence of cardinal signs of the disease is shown below:—

Case	Dermatitis	Stomatitis	Diarrhoea	Mental symptoms	Achlorhydria
1	+	—	+	?	++
2	+	+	—	?	+
3	+	—	+	?	++
4	+	+	—	+	+
5	+	+	+	+	++

The fractional gastric analysis showed achlorhydria in all five cases, in three even after histamine.

All were anæmic, in one case the anæmia was persistently microcytic (even after treatment), in two it was normocytic, and in two macrocytic.

All improved rapidly on hospital diet and marmite. In one case campolon was given as the patient wished to leave hospital early, and the recovery was dramatic in its rapidity. In no case was nicotinic acid given as this substance did not become available in India until the last of these cases was already under treatment.

A NOTE ON PELLAGRA WITH SPECIAL REFERENCE TO THE DISTRICT OF KANGRA (PUNJAB)*

By NAND LAL BAJAJ, L.S.M.F.

In charge, Civil Dispensary, Kangra

PELLAGRA is a very important disease in India and particularly in this part of the country, namely, the Kangra valley. My object in reporting these few cases is to stimulate interest in the subject.

Space will not allow a full discussion of the aetiology of this disease, but it is universally acknowledged to be a dietetic disease. The main dietary deficiencies associated with it are good quality protein and vitamin B₂, the pellagra-preventing vitamin. The disease is common amongst maize eaters, as maize provides a poor protein with certain important amino-acid deficiencies.

The cases reported below bring out certain of the important points in the aetiology, symptomatology, and treatment of this disease. In every case the patient gave a history of eating corn bread.

Case 1.—Hindu female, aged 50 years, a member of a poor peasant family, was admitted on 16th March, 1937, complaining of:—

- (i) Disfigurement of the hands and feet.
- (ii) Soreness of the mouth.
- (iii) Indigestion.

Duration—one year.

Present condition.—Dorsum of hands, feet and extensor surface of the lower parts of the forearms and legs cracked here and there, with some pigmented and depigmented patches over them. Skin slightly thickened. Some smarting felt by the patient at times over the affected parts. Epithelium absent from the dorsum of the tongue to a great extent. Ptyalism marked. Pallor marked.

Treatment.—(i) Sodium thiosulphate 10 per cent solution, 10 c.cm. intravenously daily. (ii) Potassium permanganate gargles. (iii) Acid, iron and arsenic tonic mixture. (iv) Campolon injection every other day. (v) 'Yeast vite' tablets 4 per day. (vi) Wheat bread, milk and dāl.

Meat and egg refused.

Progress.—On 23rd March soreness of mouth decreased a good deal, so also pigmentation and scaliness.

On 29th March soreness of mouth decreased a good deal, so also pigmentation and scaliness.

Result.—Patient did not show much improvement in her local or general condition by the short-lived treatment. Discharged on 31st March, 1937.

Case 2.—Hindu female, aged 25 years, wife of an extremely poor farmer, was admitted on 10th March, 1938, complaining of:—

(i) Frequency of stools with blood and mucus, and griping in abdomen.

(ii) Dyspnoea: duration 2 years.

(iii) Cracked and pigmented condition of back of hands, upper surface of feet: duration 3½ years.

(iv) Salivation and swelling below the lower jaw; duration 2½ years.

(v) Slight loss of control over speech; duration 9 months.

(vi) Swelling of abdomen, feet and face; duration 6 months.

Present condition.—Condition of hands and feet typical of pellagra. Severe anæmia with hæmic murmur heard all over the heart area. Enlargement of both the submaxillary and sublingual glands due to stomatitis and some glossitis. Speech somewhat falling in character, patient stating that she could not articulate and pronounce words as she desired to do; sometimes even quite a different word uttered contrary to her intention. Œdema of feet, puffiness of face. Some fluid in abdomen. Traces of albumin in catheter specimen of urine.

Treatment.—(i) Marmite 5v *ter in die*. (ii) Sodium thiosulphate intravenously as above. (iii) Calcium and parathyroid tablets two a day, for a few days only. (iv) Metatone 5ii *t.i.d.* for a few days. (v) Neo-hepatex intravenously—20 c.cm. in all. (vi) Iron tonic mixture as above but started before metatone. (vii) Whitfield's ointment (salicylic acid and benzoic acid 4 per cent each) for hands and feet. (viii) Chromic lotion, 1 per cent paint, for stomatitis daily for some days.

Diet.—Mostly milk for the first three weeks, later wheat bread and some vegetables and curd added.

Progress.—13th March. Swelling of the face and hands, etc., decreasing.

20th March. Appreciable improvement in general physique. Scales vanishing, and salivation and frequency of stools decreasing.

28th March. Improving steadily.

4th April. Feels markedly relieved. Only two or three stools, free from blood and mucus, a day. Condition of skin of hands and feet nearly normal in appearance.

Patient showed marked improvement in general and local condition. Diarrhœa vanished towards the end and patient may for all practical purposes be regarded as cured.

9th April, 1938. Discharged.

Case 3.—Hindu female, aged 27 years, husband in forest service. Fairly poor. She was admitted on the 6th April, 1937, complaining of:—

(i) Soreness of the tongue and inside of cheeks; duration—5 months.

(ii) Gurgling and pain in abdomen with occasional diarrhœa: duration—1 month.

Present condition.—A few white raised spots on the inner side of the cheeks, mucous membrane red and glazed in patches, mucous membrane of tongue denuded of epithelium over large areas. No enlargement of glands draining the affected parts. Stools rich in undigested food material.

Note.—About one month after her discharge from the hospital as cured, I was informed that the patient had gone insane, and the picture as described to me was more or less one of dementia. She was perfectly cured of this too in six months' treatment and is now absolutely all right.

Treatment.—Sodium thiosulphate, iron tonic mixture, neo-hepatex as above. Potassium chlorate and permanganate for gargles (as a placebo). Two to three raw eggs a day. Green gram 2 to 6 ounces daily. Plenty of milk and less of bread, mostly wheat, no maize at all.

11th April. Feels better than before, gets rectal tenesmus at times.

17th April. Condition of mouth and tongue certainly much better than before.

26th April. Patient feels vastly better and her tongue and mouth appear normal.

1st May. Practically cured.

Result.—Patient discharged cured on 2nd May.

Case 4.—Hindu male, aged 48 years, a farmer, was admitted on 3rd June, 1938, complaining of:—

(i) Extreme weakness with tingling and numbness over the entire body.

(ii) Scaliness and pigmentation of the back of the hands and upper surface of feet and legs extending upwards for a few inches in both the extremities.

Duration—one month.

Present condition.—Clinical features did not reveal any definite organic lesion of the nervous system, the involvement of which might have become manifest should the treatment have been postponed for some days more. Condition of the skin of the hands, etc., was typical of pellagra. History of taking corn bread for prolonged periods.

Treatment.—Neo-hepatex given freely as the patient wanted to leave the hospital very soon. The rest of the treatment consisted of marmite, iron tonic mixture, and avoidance of corn bread, plenty of milk and eggs.

Progress.—6th June. Feels much stronger than before.

10th June. Much better as regards his physical strength and the condition of cutaneous lesions.

Result.—Patient left the hospital on 13th June, considering himself cured as regards his general health which improved wonderfully rapidly although a few scales still could be seen on his hands.

Case 5.—Hindu male, aged 50 years, a zemindar, was admitted on the 1st July, 1938, complaining of:—

(i) An eruption on the upper and lower extremities.

(ii) Tingling sensation and slight numbness of the feet and legs.

(iii) Occasional diarrhœa: duration 3 months of each.

(iv) Pain in shoulder joints: duration 3 weeks.

Present condition.—Slight œdema of dorsum of feet and great bodily weakness due to accompanying anæmia. Cutaneous involvement was quite typical, but it extended from the last finger joints and the last toe joints to well above the elbows and middle of the front of the thighs, respectively. Slight dulling of sensation, particularly the superficial cutaneous of both the lower extremities.

Treatment.—Iron tonic mixture; salicylic acid ointment (4 per cent) for local lesions of the skin; sodium thiosulphate injections; usual diet.

Progress.—3rd July. Patient did not show any noteworthy improvement in his short stay in the hospital.

Results.—Patient could not afford injections of neo-hepatex and left the hospital too early to permit other therapeutic measures to be fully tried.

Case 6.—Hindu female, aged 24 years, wife of a poor shop-keeper, was admitted on the 3rd July, 1938, complaining of:—

(i) Burning pain inside the mouth: duration one year.

(ii) Salivation: duration one year.

(iii) Difficulty in swallowing: duration six months.

(iv) Swelling below the lower jaw: duration six months.

(v) Inability to speak properly: duration six months.

(vi) Amenorrhœa: duration two years.

(vii) Diarrhœa and diminished appetite for several months.

Present condition.—Mucous membrane of the whole of the interior of the oral cavity was red and congested, tongue slightly swollen, papillæ and epithelium gone over the anterior 1½ inches of the dorsum of the tongue. Swelling below the lower jaw consisted of enlarged and slightly tender submaxillary and submental glands. Back of hands and dorsum of feet showed slight pigmentation and cracking. Slight roughness and darkening of skin of the back of the neck and face. Speech slow and slurring. Father-in-law of the patient and her own three children died of prolonged weakness and stomatitis. No history or evidence of venereal disease.

Treatment.—Neo-hepatex 2 c.cm. injections intravenously, 24 c.cm. in all. Nicotinic acid started on 9th July, 1938, as an experiment for the first time, from 30 to 180 mgm. a day orally alternating with 30 mgm. by the intravenous route, the drug thus being administered daily. One per cent chromic lotion locally for

stomatitis. Whitfield's ointment locally. Germinating gram from one to eight ounces a day, curds, 2 pounds of milk, butter. Stale wheat flour bread. Abstinence from corn bread which the patient always took sumptuously and enjoyed. In all 2,100 mgm. of nicotinic acid were given.

Progress.—9th July. Excessive perspiration and pains all over the body, lasting for two or three hours only, followed nicotinic acid injection 30 mgm. intravenously.

12th July. No benefit so far. No untoward effect of nicotinic acid.

22nd July. Shows improvement in all respects.

23rd July. Feels very much better, stomatitis markedly relieved. Again got pains with nicotinic acid injections.

Appearance of skin approaching normal.

Result.—The condition of the affected skin restored to normal. Patient regards herself cured in all respects, though still has amenorrhoea. Tongue still looks glazed over a small patch: speech normal.

Discharged 1st August, 1938.

Treatment.—All cases should be treated in hospital if possible, even moderately severe cases, as it has been found that a prolonged course of treatment is essential to improve the general, as well as the local, condition of the patient. Moreover, changes of environment help a good deal in the cure.

Diet.—Maize should be totally forbidden. Substances containing protein of high biological value and high vitamin-B₂ content are essential for the patient.

For detailed information regarding the nutritive value of Indian food substances, *Health Bulletin No. 23*, now available in almost all hospitals and dispensaries, should be consulted. Of the cereals, wheat flour is the best; of the pulses, black gram, green gram, red gram (*dāl arhar*) are quite rich in vitamin B₂. Soya bean is also a very good source of vitamin B₂ and proteins, though not available everywhere. Sprouted pulses contain also a certain amount of this vitamin. Amongst the vegetables, potato tops the list in its vitamin-B₂ content, though lady's fingers and tomato also contain some. Luckily, all these three vegetables are fairly abundantly grown in the hills, although not used so much by the inhabitants of this poor district.

Other substances which have been found lacking in the diet of pellagrins, but which are very good sources of proteins and vitamin B₂, are milk, curds, skim-milk powder, ground nut, dates, meat and some fresh fruits and vegetables, though not all.

Medicinal treatment is mostly symptomatic and extremely important too. For its being very rich in vitamin B₂, yeast is universally prescribed; marmite to the extent of an ounce should be added to the patient's diet. It is good for improving the patient's appetite for which we can also prescribe dilute hydrochloric acid and Fowler's solution, as there is hypochlorhydria. Marmite is comparatively cheap and rich in the pellagra-preventing factor of the vitamin-B complex.

Some reliable preparations of liver, e.g., neo-hepatex, having proved of great assistance in strengthening the constitution of pellagrins in my

hands, should invariably be administered to those who can afford it. It curtails the period of treatment, improves the appetite, removes debility, and even relieves stomatitis.

Mention must be made of a new drug tried fairly extensively for pellagrins by American clinicians, namely nicotinic acid. It is stated to be precursor of the PP (pellagra-preventing) factor of the vitamin-B₂ complex. Vitamin B₂ contains three important substances, (1) lactoflavine, (2) vitamin B₆, the rat dermatitis factor, and (3) the PP or pellagra-preventing factor.

I have tried it only on one patient and found it very helpful in improving the local condition of the mouth and the skin. It is a useful adjunct to other parts of the treatment. It cannot, in my opinion, replace the diet regime. A well-balanced diet is indispensable, particularly one rich in proteins and vitamin B₂, but comparatively poor in carbohydrates. No untoward effect was seen even with 210 mgm. a day by mouth and 60 mgm. intravenously. It should be tried on all patients, provided the cost can be reduced a little.

As the patients regard their trouble mainly as local, something ought to be applied locally to the skin and interior of the mouth, e.g., boroglycerine or chromic lotion 1 per cent for stomatitis, astringents for diarrhoea, salicylic ointment four per cent, or some other drug for removing scales from the affected skin of the limbs.

It must never be forgotten that no amount of local treatment will prove of any avail unless the rest of the treatment, especially the dietetic, is strictly carried out.

For improving the appetite and impoverished condition of the blood, ordinary tonics, such as quinine, arsenic, strychnine, and iron should also be prescribed in suitable doses.

Out-patient cases.—Nine cases were treated in the out-patient section of my dispensary. They offered little difficulty in diagnosis which was purely clinical; elaborate laboratory aid is neither available here nor indispensable for diagnosis of pellagra, of which there are many cases even in *tehsil* Hamirpur in the district of Kangra, judging from the fact that almost all the cases seen belonged to this *tehsil*. Nearly all of them were free from nervous manifestations, except a boy about eight years old who had been ailing for three years according to the statement of his parents. He showed evidence of combined postero-lateral degeneration of the cord and could utter only a few words. Mentally he was somewhat dull and peevish in nature. His cutaneous lesions extended up to the middle of his limbs.

All these out-patient pellagrins had modified treatment. It was emphatically impressed upon them that corn bread was bad for them, as it lacked vitamin-B complex which is so very essential for maintaining the integrity of the whole body, particularly of the gastro-intestinal

(Continued at foot of next page)

A MICROSPORUM NEW TO INDIA

By P. A. MAPLESTONE, D.S.O., D.Sc., M.B., B.S., D.T.M.
and

N. C. DEY, M.B., L.T.M. (Cal)

(From the Medical Mycology Inquiry, under the Indian Research Fund Association, School of Tropical Medicine, Calcutta)

In India, microsporon infection of the scalp is uncommon amongst children residing in the plains. Practically all the cases we see are European and Anglo-Indian children coming from hill-station schools and as far as we know no case has been reported in an Indian child. Out of 177 cases of ringworm of the scalp clinically and mycologically investigated in the Calcutta School of Tropical Medicine, sixty (51.3 per cent) were caused by microsporon infection. This figure represents only a certain percentage of the cases as all the infected children are not sent down from the hill station schools at the time of an outbreak.

We saw recently several children from Shillong with microsporon infection of the scalp and the material obtained from these cases forms the basis of our present study.

On the 3rd September, 1936, a girl came from Shillong for the treatment of ringworm of the scalp, and on the 2nd and 12th November of the same year two more girls from the same institution attended for the treatment of a similar affection.

On microscopic examination, infected hairs showed evidence of microsporon infection and on culture the same type of growth was obtained from all these cases; but they were different from *Microsporon audouini*, the species usually infecting the scalp.

(Continued from previous page)

tract, and that this deficiency in diet is a common cause of diseases like diarrhoea, vomiting, achylia, anaemia, constipation, colitis, sprue, pellagra, lack of vigour, and impaired growth. The dire need for taking a diet derived from animal food rich in proteins but poor in carbohydrates was pointed out to them. They were very clearly given to understand that they were being underfed and so also their children, whose heights and weights were disproportionate, most of them being under-weight. The names of the articles that they should take and should not take were given to them.

Unfortunately, these patients did not appear for treatment more than twice or thrice each, probably because with general and dietetic treatment their immediate troubles were overcome.

Acknowledgments

My thanks are due to Dr. G. W. Hardy, my civil surgeon, for kind permission to publish this paper. Dr. Mohan Lal Pathak, in charge Jail and Police Hospital, Dharamsala, also deserves my indebtedness for certain really useful suggestions.

During that period four boys from another school in Shillong also attended and were found to be infected with *M. audouini*.

At our request, Major Haythornthwaite, I.M.S., kindly sent specimens of hair from all the cases suffering from ringworm of the scalp in both institutions; and five specimens were received of which three were from the girls' school and two from the boys' school.

Six specimens were studied from each school and microscopically all of them showed evidence of microsporon infection. On culture all the specimens from the girls' school showed growths of the same character; they were different from

Fig. 1.—Photograph showing a single patch on the right parietal eminence.

those from the boys' school which were *M. audouini*.

On the 9th of March, 1937, an Anglo-Indian boy from a school in Calcutta attended for treatment of ringworm infection of the scalp which was found to be similar to those from the Shillong girls' school. When this fungus was isolated an enquiry was made if the boy had visited Shillong and it was found that he was one of a party who went to Shillong for a time and returned to Calcutta in July 1936. He mixed freely with the school children while there.

Clinical characters of the lesions

Out of seven cases of this infection (six from Shillong and one from Calcutta) four attended personally and in the remaining three cases material was received by post. In the four

cases examined the lesions were of the same character. The ages of the patients varied from six to nine years. The size of the patches varied from a tiny spot infecting a few hairs to patches two or three centimetres in diameter. The patches were covered with dry, greyish-white scales, and the infected hairs, which were broken a little above the surface of the skin, could be plucked out easily. These hairs had greyish-white sheaths at their roots, like those infected with *M. audouini*, so there was nothing whereby they could be distinguished clinically.

Microscopic appearance of the hair

Under a cover-slip preparation with a solution of sodium sulphide the size of the spores was

Fig. 2.—Photomicrograph of a hair cleared in sodium sulphide solution ($\times 450$).

found to be from 2.4 to 3μ in diameter. The spores gave a mosaic appearance like that of *M. audouini* (text-figure 2). Mycelial elements were few and they were of the same diameter as the spores.

Cultural characters

Primary cultures: Primary cultures on Sabouraud's test medium.—The culture appears on the sixth or seventh day after inoculation at room temperature (diurnal variation 18°C . to 30°C .) as deep brown or brownish-yellow spots. There is slight surface growth and the submerged growth spreads in the medium in an arborescent and radiating manner. The length of growth varies from 0.5 to 1.25 cm. in six weeks (plate IX, figure 1). It is very slow when compared with that of *M. audouini*.

Primary culture on Sabouraud's conservation medium.—The growth at room temperature appears

on the seventh day after inoculation with the infected hair. It becomes slightly elevated above the surface of the medium and is covered with a thin layer of white, chalky powder except for a narrow ring on the

Fig. 3.—Drawings to show terminal chlamydospores in hanging drop cultures ($\times 500$ approx.).
(a) Our fungus.

(b) *Microsporon ferrugineum*.

margin which is smooth and brown in colour. The size of the growth is 0.4 to 0.8 cm. in diameter (plate IX, figure 2).

Subcultures.—Subcultures on most of the laboratory media show two types of growth, namely, a faviform

one (plate IX, figure 4), the surface of which is covered with brownish-white powder or a flat type which is flush with the surface of the medium. When the surface growth is abundant the faviform appearance is well seen in flask culture in Sabouraud's medium, but when the surface growth is small or absent a flat type of growth occurs with lanceolate rays in the medium. An intermediate type is also found in some specimens when there is an elevated surface growth in the centre and a flat growth at the periphery.

On successive subcultures the pigment is gradually lost in some specimens and the growth is also a little more profuse than the primary culture. Results of subcultures on different laboratory media are given in detail below.

The character of the growth on different laboratory media six weeks after inoculation

Sabouraud's test medium with maltose, pH 6.—Either type of growth may occur. Size 1.5 to 2 cm.

Sabouraud's medium with glucose, pH 6.—The first type of growth is often noticed and in some cultures sulphur yellow powder appears at the centre of the growth (plate IX, figure 3).

Sabouraud's conservation medium pH 6.—The character of growth is like that of a primary culture except that there are a few radiating furrows on the surface. Size 1 to 1.25 cm. in diameter.

Glucose agar pH 7.6.—On this medium surface growth is commoner than the flat and transitional forms. The growth is slightly convex and brown in colour. The surface is crossed by multiple, shallow radiating furrows and is covered with fine brownish-white down. In a transitional type the centre is folded or depressed with flat growth at the periphery. Size 3.5 cm. (plate IX, figure 5).

Glycerine agar pH 7.6.—The growth is flush with the surface of the medium and the colour varies from a dark brown to a light brown shade. From the inoculum, lanceolate radiating rays are distributed in the medium. In some cultures the surface shows fine white velvety down. Size 2.5 to 3 cm.

Nutrient agar pH 7.6.—The growth is like that on glycerine agar except that it is lighter in colour and the rate of growth is slower.

Blood agar.—The flat type of growth occurs in this medium. There is a narrow margin of hemolysis round the growth. Size 2 cm.

Inspissated serum.—The growth is smooth and becomes slightly wrinkled with age. Size 1.5 to 2 cm. It is slightly proteolytic.

Dorset's egg medium.—The character and rate of growth is like that on inspissated serum but there is fine velvety down on the surface.

Potato medium.—The growth in this medium is slightly convex and the centre is slightly mammillated. The colour is brown and the margin often has a deep brown or chocolate shade. Size 1.5 to 1.5 cm. (plate IX, figure 6).

*Bacsa medium pH 6.**—The surface growth is often profuse, and flat growth is rarely seen. In a culture where the surface growth is profuse the centre is elevated above the surface of the medium and is covered with brown or sulphur-yellow powder. It is traversed by a few shallow radiating furrows. Round the central elevated portion there is a flat submerged growth. The central growth is about 1.25 cm. in diameter and the whole varies from 3 to 3.5 cm. (plate IX, figure 7).

Synthetic medium (Czappek's solution with agar) pH 6.—There is only slight submerged growth and the size varies from 0.75 to 1 cm.

Natural media.—Culture on wheat, barley, paddy, rice, etc., gives no appreciable growth.

Action on sugar.—No change has been observed in ordinary laboratory sugars; glucose, maltose, mannite, dulcitol, saccharose, salicin.

Action on milk.—No proteolytic change has been noticed in milk.

Anaerobic culture: On Sabouraud's test medium.—The growth is elevated above the surface of the medium and the surface is covered by a dense uniform layer of dirty white powder and is marked by multiple radiating furrows. The deep surface shows a deep brown or a light chocolate shade. Size 0.75 to 1.25 cm.

Complete anaerobiosis.—Under completely anaerobic condition in MacIntosh and Fildes's jar, no growth has been observed during a period of three weeks.

Mycology

The separate mycelia are 2 to 3.2 μ in diameter with dichotomous branching. Sessile aleurospores are very occasionally seen. Atypical mycelial racquets are often present. Intercalary chlamydospores are generally isolated but are found in short chains occasionally. Terminal chlamydospores may be found, oval or spindle-shaped and vary from 20 to 30 μ or rarely up to 35 μ in length. Formation of septa in the terminal chlamydospores has not been noticed. Pectinate hyphae are rare.

Pleomorphism.—No pleomorphism has been noticed when subcultures are carried on at intervals of two months.

Animal inoculation.—Cultures from the seven original cases were all used in these experiments and they were all negative on guinea-pigs, mice, rats, rabbits and monkeys. Controls on guinea-pigs with *M. ferrugineum* and *M. andouini* were also negative.

Spread of infection.—The infection appeared to have spread amongst the inmates of the boarding school through direct contact, as we could not find any animal likely to act as a carrier.

Discussion

All the cases so far studied were similar and showed clinical evidence of microsporon infection of the scalp. Microscopically the hair showed small spores with typical mosaic distribution similar to that of *M. audouini*. The cultural characters resembled those of *M. ferrugineum* Ota, 1921. The primary culture showed a colour resembling that of *M. ferrugineum* but the typical deep yellow colour, characteristic of *M. ferrugineum*, was absent in our subcultures, moreover our cultures were not glabrous as they are in *M. ferrugineum*. On the contrary cultures of *M. ferrugineum* may give a brown or chocolate colour as obtained in our cultures. On potato and Bacsa media the growths of *M. ferrugineum* and our fungus were very much alike and on Sabouraud's glucose agar a sulphur-yellow colour appeared.

Regarding the morphology we made a detailed study of our fungus in comparison with *M. ferrugineum*, and no differences were discernible.

Inoculations on laboratory animals were negative.

EXPLANATION OF PLATE IX.

In view of the above facts it appears that this microsporon is possibly a variant of *M. ferrugineum*.

Summary

1. Seven cases of microsporon infection of the scalp caused by a fungus hitherto unknown in India have been recorded. The clinical, microscopical and cultural characters have been noted.

2. Culturally it grows slowly and shows chiefly two types of growth—a raised faviform type and a flat type.

3. The type of growth resembles that of *M. ferrugineum*.

4. The colour of our cultures was various shades of brown whereas brown has only occasionally been recorded in *M. ferrugineum* in which deep yellow is the most usual.

5. The morphology is similar to that of *M. ferrugineum*.

6. This fungus is possibly a variant of *M. ferrugineum*.

Acknowledgment

We acknowledge the receipt of cultures of *Microsporon ferrugineum* kindly supplied to us by Professor Ota of the Faculty of Medicine of the Imperial University of Tohoku, for comparison with our species.

Treatment

Out of seven cases recorded three were treated by us. The first case had multiple patches on the scalp and was treated with x-rays. An epilation dose was administered after the technique of Adamson. Twenty-one days after the exposure, while there was a partial epilation, a patch two inches in diameter was noticed behind the left ear and was treated with the following preparation applied twice daily :—

Thymol	gr. x
Oil of cinnamon	ms. x
Liquor iodi mitis	oz. i

Along with this application manual epilation was done and the patient was discharged cured in about three weeks.

The second case showed a few tiny spots and was treated with the application of the same paint along with manual epilation. He was discharged cured in a month.

The third case had a single patch on the right parietal eminence about two inches in diameter and was treated for three months with the above paint. As the patient was improving satisfactorily she left Calcutta with a supply of the paint and necessary instructions. About three months later she came back with multiple patches on the scalp. The same paint was continued for two months along with manual epilation. Her hair was clipped short to find if there were any newly infected patches. As the progress was slow 2 drachms of glacial acetic acid was added in an ounce of the above prescription. The patient was discharged cured, after using this new application for three months.

OBSERVATION ON THE PATHOLOGY AND THERAPY OF THE SO-CALLED FRONTIER SORE

By H. J. HAMBURGER, M.D. (Hamburg)
Gordon College, Rawalpindi

Introduction.—In his report on 'A limited outbreak of diphtheria exhibiting both cutaneous and faucial lesions', Bensted (1936) says that the patients under observation sustained some sort of abrasion in climbing up or scrambling down the steep rock-strewn *khud*-side. The wounds appeared to be trivial, but did not heal. That this non-healing did not attract attention earlier may be explained by the fact that a condition very similar in appearance is very common in this area (North-West Frontier Province). It develops from a simple abrasion and is often very slow to heal. The aetiological agent in the majority of cases appears to be a staphylococcus, but it is probable that several factors are responsible for the slow healing. The lesion is often referred to colloquially as Frontier sore, but is not to be confused with the Leishmania infection that on occasions has been known by that name.

Subject of this research.—As Bensted indicates, it is very difficult, if not impossible, to make clinically a difference between a chronic sore with or without diphtheria. It seems equally difficult, as the history given is usually not reliable, to differentiate between this clinical complex of chronic sores and the real Leishmania infection, once the oriental sore is broken down. The great number of cases with these chronic ulcerations of the skin give the impression of a low virulence of the infecting agent. Nevertheless they are resistant to routine treatment. That induced us to collect data as to the pathology and therapy of the condition.

We carried out investigations to find what part the various micro-organisms take in the aetiology of the chronic minor septic conditions of the skin, occurring in this area. We tried to define any further aetiological factors, and finally we controlled the results of various treatments, selected with a view to being as specific as possible. The results of the laboratory work we worked on the following hypothesis : The Frontier sore is to be regarded as a clinical entity. It can be divided into several aetiological groups, each of which requires a treatment of its own.

Method.—From December 1937 to October 1938 we collected 88 cases from Rawalpindi, Tonk in south Waziristan, Taxila and Sialkot, that is from places under similar climatic and geographical conditions in the north-west Punjab and North-West Frontier Province.

Each case was examined first for Leishman-Donovan bodies. An intramuscular needle, applied to a record syringe, was inserted from outside towards the ulcer, until the point of the needle almost reached the margin of the ulcer.

A few droplets of serum or tissue fluid without blood were withdrawn. Those were placed upon a slide, made into a film and stained in the usual way after Giemsa or Leishman. Repeated examination in cases in which leishmania had been found showed us that the parasites will be unfailingly revealed by this method.

The next step was the bacteriological examination. Normal saline was applied for 24 hours

On the whole, the condition cannot be considered as presenting a very typical or striking clinical aspect. In the selection of our cases we have been guided more by the chronicity and obstinacy to treatment than by the clinical appearance. The number of cases collected from the various places and the micro-organisms recovered from the sores are shown in the first table :—

TABLE

Place	Number of cases	With leishmania	With KLB	With <i>Staph. aureus</i>	With <i>Staph. albus</i>	Streptococci	Others and sterile
Rawalpindi ..	47	6	3 *	21	10	2	..
Tonk (South Waziristan)	19	0	0	6	8	3	..
Taxila ..	8	2	0	4	1	0	..
Sialkot ..	14	1	0	0	3	0	..

* Two proved virulent.

Not examined, 5.

and with a swab material taken from the surface of the ulcer. Incubation was made as a rule on Löeffler's medium, sometimes on Löeffler slopes as well as on blood-agar plates. Subcultures and biological assays were made as required by the bacteriological methods. The examination for leishmania was carried out in each case, the bacteriological examination in the majority of the cases.

Inquiries as to the history of the case were made. Location, size, and clinical appearance of the sores were noted, a physical examination of the patient undertaken and his diet investigated. These data were put onto a printed form on which space was provided for follow-up observation. This form was filed with the clinic or hospital that attended to the patient and collected after the patient's discharge. A corresponding chart with the microscopical proceedings was kept at the laboratory. That is the material underlying this study.

Results.—This is the clinical aspect of the affection under observation: the sores may be single or multiple. There is a certain predilection as to location in so far that the trunk is less frequently affected, while the palms and soles were not found affected. The discharges frequently form brown crusts, under which a shallow ulcer lies with sharply-cut vertical edges. Frequently this ulcer forms the top of an indurated and elevated area. Sometimes the ulcer is found clearly cut into the healthy skin. The surroundings of the ulcer show, especially in the cases with induration and elevation, a pale pink or bluish cyanosis. Frequently, in the older cases, an atrophy of the epidermis is noticed, giving it the appearance of cigarette paper. Sometimes these atrophic parts are covered with fine, white scales. The size of the ulcers varies from $\frac{1}{2}$ to $2\frac{1}{2}$ inches.

We have found that the aetiology of the Frontier sore cannot be described by mentioning one single germ or parasite. The Leishman-Donovan body, the traditionally accused agent, totals only about 11 per cent.

The seasonal distribution of the cases, as they were admitted for treatment, is shown in the

graph. The apparent increase in the number in the late autumn and late spring corresponds with the empirically gained opinion of medical men in this area. It should however be considered as open to certain doubts, as some cases do not come under observation until many months after the beginning of the affection.

The duration of the condition prior to admission under our control was found to vary from 5 years to 14 days. Only sores which had not shown a tendency to heal after at least 2 weeks of routine treatment were considered suitable for this investigation. The average duration, however, was about $2\frac{1}{2}$ months.

There was reason to suspect that some nutritional deficiency might be one of the causative factors of this chronic condition. Careful inquiry in each single case as to the diet revealed the fact that only in 6 cases was a diet offering little variety taken which could be called deficient in its vitamin-C content. No evidence for

caloric underbalance or lack of other vitamins or minerals could be found. It was rather noticeable that the condition occurs in people clinically otherwise completely healthy.

Two cases in which staphylococci had been found were treated with vitamin C, orally and by injection, but the sores did not respond to this treatment. One case had a diet with insufficient vitamin-C content, the other had a normal diet.

In several cases, a microscopical examination for a fungus was undertaken, in order to pursue the etiological research in as many directions as possible. In only one case was a fungus found. This, after histological examination, proved to be an initial actinomyces of the skin. Where it appeared necessary from any point of view, an examination for tubercle bacilli and the Wassermann reaction was undertaken. Cases in these categories are not considered here. We regret that no facility was available to examine the sores as to a possible virus as an agent. From the results compiled it seems still possible that a virus may be the primary agent in the cases which are not due to leishmaniasis. Research into this question will be carried out as soon as the necessary facilities are available.

It has been found that the history does not often help much in the diagnosis. Only about one half of all the patients were able to give us any information as to the very first symptoms. In 10 cases mosquito or other insect bites were made responsible; none of these cases showed leishmania. If there was a definite history of a trauma, leishmaniasis can be regarded as being ruled out. Oriental sore, *sensu strictiori*, can be recognized when in the stage of the initial papule, but once broken down, the microscopic examination is the only sure help in the differentiation. Even that will fail in very old-standing or previously-treated cases.

Treatment.—We desired that in the treatment of the collected cases those methods should be employed which were the most specific ones regarding the nature of the micro-organisms revealed in the sores.

1. This was easiest in the cases of eutaneous diphtheria. One case healed rapidly with intramuscular injection of antitoxin (20,000 units) and dressing with the antitoxin, within 7 days. Another case took one month before it healed. Conclusions as to the effectiveness of the treatment cannot be drawn from our three cases.

The necessary subcultures, to obtain a definite bacteriological diagnosis, were carried out, and in two cases virulence tests which guinea-pigs were undertaken which were positive.

2. Out of the 9 cases of oriental sore, 7 could be followed up as to the result of the antimony treatment. Five cases had treatment with Fouadin; four healed after 10, 10, 7, 5 injections, respectively. The injections were given daily or on alternate days. The initial dose was 0.5 c.cm., thereafter the regular dose was 1.0 c.cm. for each kilogramme of body weight. One

case after 6 injections showed no signs of improvement. Two cases were treated with neostibosan; one showed only slight improvement after 10 injections of 0.3 gm. of this pentavalent antimony compound. The initial dose was 0.2 gm.; one injection of 0.45 gm. was given, but not tolerated.

It would be well worth while to decide in a longer series of oriental sores, if the pentavalent or the trivalent compound is more effective. Fouadin, the antimony-pyrocatechin disulphonate of sodium, has acted well. It seems desirable indeed to put it to further clinical trial.

3. The great number of cases remaining after leishmania and KLB cases had been ruled out offered a difficult therapeutical problem. We observed before the beginning of the therapeutical studies dealt with in this communication, 21 cases under various treatments. Copper sulphate and lactic acid, ichthyol, various other antiseptic and stimulant local applications produce sometimes favourable, sometimes no results at all. In 50 per cent of the cases of this series the ulcers were not healed after three weeks. General treatment was employed, such as vitamin C, given as mentioned above. Antimony preparations were applied, regardless of whether leishmania were present or not. It seems impossible to compare all the previous treatments in view of the results obtained in the cases studied in this report. This first series showed us that the state of the treatment of the condition under discussion was unsatisfactory. In 50 per cent there was no visible result within 2 months of treatment; the rest needed in a few cases one week, but the average was 3 to 4 weeks for recovery.

We decided to make an experiment with a local application of the new bactericidal substances of the sulphonamide group. Our observation has shown us that their antiseptic power fortunately is combined with a stimulating power which produces granulations and epithelial growth.

We are well aware of the possibility of pharmacological and toxicological differences in the action of the various chemicals containing sulphonamide groups (para-amino-benzene-sulphonamide). There seems now to be evidence available showing that the affinity of the many sulphonamide-containing substances to certain tissues is not always the same. Our experiments, however, are not extensive enough to contribute new information about these difficult questions. We agree with Cokkinis (1938) who says 'So much has been written upon the subject of the "new chemotherapy" and it is still impossible to dogmatize about it'. We shall therefore report our observations without joining in the discussion of unsolved problems of the chemotherapeutical research.

Messrs. Bayer have kindly produced upon our request a 5 per cent ointment with a prontosil base (4-sulphonamide-2', 4'-diamino-azobenzol). As there is very little literature available here

we are not in a position to give references in regard to prontosil in local application or in an ointment. Lately, upon our quest for a sulphonamide preparation convenient for local application, Messrs. May & Baker have supplied us with some samples of their 6 per cent soluseptasine ointment (disodium-phenyl-propyl-amino-benzene-sulphonamido-dilusphonate). I find the literature does not contain any reports about work with this ointment. The manufacturers, however, received some communications regarding the efficacy of this preparation in case of streptococcal infections of the skin*.

We have been able to examine and follow up the effect of local application of prontosil rubrum (diaminoazo-benzol-sulphonamide), prontosil soluble (disodium-acetyl-amino-oxynaphthalene-disulphonate) and soluseptasine (disodium-phenylpropylamino-benzene-sulphonamido-disulphonate) in 45 cases of Frontier sore with non-specific bacterial flora. In the table are given: the type of germ found, the duration of the disease before administration of sulphonamide was started, the period after which complete healing was reached, i.e., restoration of the subcutaneous tissue and epithelium. Furthermore the number of applications and the form in which the individual drug was given are indicated. The average duration of the affection before the described treatment was given was 2½ months. One case of 5 years' duration was not taken into account. Healing occurred in 40 cases out of 45. The average time needed for treatment was 7.5 days. The average number of applications was 4.25.

* After I had sent the paper to the press, the following publication regarding prontosil in local application came to hand:—

K. H. Jaeger (1936) reports that in infective diseases of the skin, for instance whitlows and furuncles, a few prontosil dressings diminish the secretion and promote granulation formation. Prontosil was especially effective in abscesses of the sweat glands which had previously been treated for months without results. This I can confirm from my own observation.

Jaeger further saw favourable results from prontosil when applied to dirty sport and street wounds. The same observation was made by Sigel (1936).

Jaeger used prontosil in local application also for certain forms of eczema. He painted the affected areas with a saturated solution from the tablets with equal parts of alcohol and acetone. Weeping dermatitis responded better to prontosil ointment, 2 to 5 per cent prepared with lanoline and liquid paraffin.

Merz (1937) used a 10 per cent ointment which improved rapidly acne, furunculosis and impetigo contagiosa.

J. F. P. Gallagher (1938) obtained successful results in the treatment of erysipelas and acute dermatitis by using as a local application prontosil red, 7½ grains being dissolved in 1 ounce of distilled water. He says that the value of this preparation in local application should not be overlooked.

Report of a few outstanding cases:—

Case 1.—Baker, aged 24 years, male. Ill for one year with a sore at the ulnar side of the right wrist. No accident or insect bite. A small area of irritation upon which a vesicle formed.

General examination does not reveal anything pathological. Mixed varied diet, with fresh fruit and vegetable, milk and meat beside the staple foods.

1½ × 1½ inches big ulcer, slightly secreting. Punched-out in an indurated area, slight atrophy of the surrounding skin. *Staphylococcus aureus*.

Three days of dressing with 1 per cent aqueous solution of prontosil soluble, the ulcer healed. Fourteen days later the newly-formed thin epithelium is strong and healthy.

Case 2.—Signalman, aged 30 years, male. Ill for one year with multiple ulcers on the back of the left foot. Started spontaneously with little boil.

General examination and diet as case 1.

Ten small ulcers in a 3 × 3 inches atrophic area over hand, indolent swelling extending over the back of the foot. The whole foot and the ankle show considerable œdema. *Staphylococcus aureus*.

After 14 days' locally applied prontosil base and 1 tablet daily twice for 8 days, the subcutaneous swelling has gone, the small defect has healed.

Case 3.—College student, aged 17 years, male. Ill for five years. Beginning with small boil.

General examination and diet as case 1.

Single 1½ × 1½ inches sore on right forearm, extensor aspect. Flat, dry punched-out ulcer, with very little underlying induration. Small areola of pink cyanosis. *Staphylococcus aureus*.

After one day's application of prontosil base ointment the old scab is removed, fresh granulations are appearing in the ulcer ground. After seven days epithelialized.

Any ill effects in general from the local application of sulphonamide-containing compounds have not been observed. There was never any local deterioration or irritation noticed. We have, as an experiment, rubbed in, for 15 minutes, all three preparations used. Afterwards, over a period of several days, we applied at the same place on the flexor aspect of the forearm the solution or ointment, respectively. No irritation or other disturbances occurred.

We propose to investigate *in vivo* the action of sulphonamide compounds upon various germs in experimental infections of the skin. *Staphylococci* do not belong to those bacteria known to be very susceptible to the new compounds. It would be interesting to find out if, in the environment of the skin, the susceptibility is changed, as compared with the blood. It will later be necessary to collect data as to the best vehicle for the chemicals and the most effective concentration. We intend and have started already to collect material about the influence of these preparations in acute infections of the skin.

Summary

1. The so-called Frontier sore is a clinical entity. Only laboratory examination reveals various ætiological groups, with leishmania, Klebbs-Löffler bacilli and a large group with non-specific common pyogenic organisms, mainly *Staphylococcus aureus*.

2. The exact microscopic diagnosis permits specific treatment for each case according to

the organism revealed. For the big group of sores with common pyogenic and contaminating organisms, compounds containing sulphonamide prove to be of efficacy in local application.

patients, to Dr. R. C. Hunsberger from the Memorial Hospital, Sialkot, and Dr. J. Samuel from Taxila Hospital for the permission for making observations on their patients.

SUPRAPUBIC LITHOTOMY

By F. R. W. K. ALLEN, M.A., D.M.,
M.A.O. (Dublin Univ.), M.C.O.G.
Civil Surgeon, Nagpur

THE method here described contains no original features but in it are combined several suggestions which have been collected from the publications of surgeons of repute. It thus appears to be superior to the operation as usually described in textbooks. In my hands it has given excellent results.

The patient is prepared in the usual manner. The largest firm rubber catheter which will pass through his or her urethra is taken and prepared as follows (figure 1). A stout sewing needle (F) is threaded with braided silk or strong linen thread (A). The needle is driven into the catheter about one inch from its base (B). The needle is then passed up the lumen of the catheter to about two and a half inches from the apex, where it is made to perforate (C) the wall and is then drawn through to the outside. Finally, the needle is driven through the tip of the apex of the catheter (D). The thread is then detached from the needle and knotted so that it cannot be withdrawn from the catheter. It is advisable to cut a couple of extra eyes (E and E, figure 2) in the catheter, which with the thread is then sterilized by boiling.

Fig. 1

Fig. 2

The patient having been placed on the table and anesthetized, the catheter is passed into the bladder, and the thread is drawn taut (figure 2). Where it emerges from the base of the catheter (A) the thread is knotted round a match, thus converting the catheter into a self-retaining one.

The bladder is now washed out with an antiseptic solution and left empty except for the stone and the loop of the catheter. A transverse suprapubic incision is made through the skin and subcutaneous tissues down to the recti muscles. The recti (figure 3) are separated and retracted

laterally. Air is then pumped into the bladder until it bulges into the wound. The peritoneum is wiped upwards until the bladder muscle is exposed. Two tension sutures are inserted into the bladder to act as retractors and the bladder

Fig. 3

is incised transversely (figure 4). The stone is removed and the bladder incision closed by two layers of continuous catgut. The recti are allowed to fall together. A thin strip of old rubber glove is left, as a drain, from the exterior of the bladder to the surface for one day only. The skin wound is closed by clips or by sutures. The patient is kept on a mixture of ammonium

Fig. 4

chloride and boric acid, sufficient being given to prevent the urine becoming alkaline, until the self-retaining catheter is removed on the fifth day. This is effected by cutting the thread where it is tied to the match.

Comments

1. Transverse skin and bladder incisions heal more satisfactorily and are less uncomfortable to the patient than vertical incisions.

2. Distending the bladder with air before incising it is much less messy than distending it with fluid.

3. The type of self-retaining catheter described cannot come out by accident.

A Mirror of Hospital Practice

URTICARIA FOLLOWING PRONTOSIL RUBRUM TABLETS

By R. L. SONI, M.B., B.S., F.R.C.S.
The Soni Clinic, Paungde, Burma

R., an Indian male, aged 31, suffered from successive crops of acute indurations of the skin. The swellings varied in size from an almond to a walnut, and had the following course: A tiny green pustule would appear at the top of an acute induration and the pus was found to contain staphylococci. Bursting of the pustule was followed by spread of œdema beyond the induration, at times the œdema being quite extensive extending from the elbow to the dorsum of the hand in a pustule on the middle of the forearm and over the greater part of the lumbar region in a pustule on the back. Local application of tincture of iodine and fomentations together with rest and evacuation of bowels with enemata relieved the condition, the œdema fading away first and then the induration. After expression of the contents of the pustules an itchy but healthy looking skin with a pigmented dot at the site of the original pustule was left, the whole process taking six to ten days. While one 'pustule' was healing, another appeared at another site, thus giving three to seven 'pustules' in various stages at one time. The patient was otherwise healthy. He had had streptococcal sore throat six months earlier which was treated successfully with prontosil album tablets.

Despite various local and general treatments, the trouble had continued for over two months. Prontosil rubrum tablets, one tablet three times a day, was prescribed. On the night following the second day of administration drenching sweats occurred and the next day the man felt very ill. In the evening mental confusion and a burning sensation in the whole body were complained of, but on examination, apart from the usual red urine and temperature 99.2°F., nothing abnormal was detected. Towards midnight he felt severe itching all over the body and could not help scratching at his skin and even pulling at his hair. His face was puffy and the skin was covered with an urticarial eruption. Oral temperature at the time was 100.2°F. Colloidal calcium and adrenalin were injected. Next day prontosil was stopped, an enema administered, and colonic lavage done and 'dimol' and 'calcionates' prescribed for oral use. The urticaria cleared by evening but itchiness persisted till next day.

On the sixth morning prontosil was again started but the following midnight urticaria recurred so it was considered to be the causative factor and was given up. Thereafter the case was successfully treated with stannous-manganese, vaccines and adexolin.

A month later when the patient was quite recovered, two tablets of prontosil rubrum were again given to test his sensitiveness to the drug and that night at 2 a.m. urticaria again distressed him though to a lesser extent than previously, but four days later when prontosil album tablets were tried nothing untoward happened.

Comments.—That there existed a direct relationship between the administration of prontosil rubrum tablets and the appearance of urticaria is quite obvious in this case from the observations that urticaria developed only following the ingestion of the drug, subsided with its stoppage and that no urticaria appeared in the intervals. I have seen three more cases where urticaria complicated the clinical picture in prontosil therapy—one in a case of erysipelas where prontosil album was given orally

and the red solution intramuscularly, another in a case of septic sore throat where only prontosil album was used orally and the third when it was used intramuscularly after abortion. But in those three cases urticaria appeared when the drug was given for a week or more. In the present instance the urticaria appeared early and, although the patient was found definitely sensitive to prontosil rubrum tablets, no sensitiveness was exhibited to the ingestion of prontosil album tablets, neither some months earlier when he was treated for streptococcal sore throat nor later when he was given a trial dose of the drug. Dietetic factors appear to be excluded, for were they operative they would act with both album and rubrum tablets of prontosil.

Summary.—A case is described where urticaria followed the oral administration of prontosil rubrum tablets though no sensitiveness was exhibited to ingestion of prontosil album tablets.

ARTHROPLASTY OF THE FIRST INTER-PHALANGEAL JOINT OF THE MIDDLE FINGER

By M. G. KINI, M.C., M.B., M.Ch. (Ortho.), F.R.C.S.ED.
Surgeon, King George Hospital, Vizagapatam
(S. India)

SPEAKING generally, the treatment of fractures in country districts is very unsatisfactory in South India. Out of 165 fractures of the metacarpals and phalanges seen from 1930-37, 85 per cent were treated as sprains and contusions in *mofussil* hospitals and by bone-setters. The result of such treatment was very marked functional disability. Any injury which occurs at the metacarpo-phalangeal or inter-phalangeal joints has to be treated with particular attention to restoration of normal alignment of fragments if normal function is to be restored. Skin or skeletal traction must be employed in cases where normal alignment cannot be easily restored. Suitable splints have to be made in order to obtain traction. When injuries to the head of the metacarpals or the base or head of the phalanges are treated as sprains the result will be stiff fingers with loss of movement and function. The stiffness of the fingers in these cases is due to mal-union. To restore the function of such fingers arthroplasty, advocated by Bunnell and McAusland, is the operation of choice. One such case was treated by arthroplasty with the results shown in the accompanying illustrations.

A male student, aged 16 years, was admitted in 1936 for stiffness and inability to flex the middle finger at the proximal inter-phalangeal joint. He gave a history of twisting of the middle finger in a domestic quarrel. This resulted in swelling, pain, tenderness and loss of function of the middle finger. He was treated in a district headquarters hospital for a sprain and later by a bone-setter with forced movements, the final result being increased stiffness.

On examination, a spindle-shaped swelling, most marked on the volar and medial aspects of the first inter-phalangeal joint of the middle finger, was found. The distal part of the middle finger was slightly

deviated towards the ulnar side. The left middle finger was shorter than the one on the right side. No movements were possible at the inter-phalangeal joint and the finger was fixed in extension. X-ray showed a stove fracture of the head of the proximal phalanx which had united in a bad position.

Treatment.—Under ethyl-chloride-ether anaesthesia, the ends of the bones were exposed by a dorso-lateral incision and excised subperiosteally after lifting the attachment of the flexor sublimis digitorum and interossei from the second phalanx. The head of the

Fig. 1.—The clinical result after arthroplasty of the first inter-phalangeal joint of the left middle finger. Note the extension of the finger.

Fig. 2 illustrates the flexion after arthroplasty.

Fig. 3.—Lateral view of the first inter-phalangeal joint showing a stove fracture of the head of the first phalanx with mal-union.

Fig. 4.—The condition after arthroplasty two years after operation. Note the concave upper end of the first phalanx and convex surface of the second phalanx at its base.

proximal phalanx was made concave and the base of the distal phalanx was made convex and the two ends were covered by fascia lata from the thigh. The wound was sutured in layers. Skeletal traction was obtained by a Kirschner's wire inserted through the distal phalanx with a special clamp made for the finger extension. A special extension splint was made by incorporating a loop of stout wire in plaster of Paris applied to the forearm.

The sutures were removed on the 10th day. On the 14th day the extension was removed and the finger was gradually flexed actively and maintained in that position until complete flexion was obtained, which

took five days. Afterwards active flexion and extension was encouraged with massage for a fortnight, at the end of which period the man went home with advice to carry on the treatment.

He reported in 1938 with the functional result shown by the pictures and the x-rays. Though the finger is definitely shorter and ugly to look at, the student has a very firm and good grip and active flexion and extension are very satisfactory.

Points of interest

Arthroplasty of the first inter-phalangeal joint is a difficult problem, because of the fact that active flexion and extension at this joint are entirely done by the flexor sublimis digitorum and the interossei, respectively. While doing arthroplasty this attachment should be carefully preserved and if it has to be detached it must be reinserted at a distal level by transplantation technique. In this case it was not necessary to do so. The insertions of the flexor sublimis and interossei were easily lifted off the bone along with the periosteum and enough bone was removed to get a gap of half an inch after excision.

AN UNUSUAL CASE OF CUT THROAT

By MIN SEIN, M.B. (Cal.), M.R.C.P. (Lond.)
CAPTAIN, I.M.S.

Second Physician, General Hospital, Rangoon, and
Lecturer in Medicine, Burma Government Medical
School, Rangoon

A Hindu male, aged 30 years, was dismissed from his appointment as a police clerk in Jaipur police station in May 1935. He came to Burma and worked as petition writer in Pyuntaza post office from where he was also dismissed. He became a *Sadhu* in December 1935 and roamed about the country. On the 8th January, 1936, some unknown men were said to have attacked him with *dahs* and inflicted a severe cut-throat wound and a large incised wound on the penis. He was said to have struggled along for three days with these injuries and reached a hut and from there he was brought by the police to Shwegyin civil hospital. The wounds were described on his history ticket as follows:—

'1. A long incised wound on front of penis, muscle deep; wound is full of maggots.

2. Incised wound $6 \times 1\frac{1}{2}$ inches and cutting the larynx and pharynx through above the thyroid cartilage'.

The wound in the throat stitched up and a laryngotomy tube inserted. The patient was very emaciated. His eyes were sunken and with the gaping throat the wound presented a horrible sight. He could not make himself understood because he had lost his voice. Only after the wound was stitched up and bandaged and the patient kept a hand on it, could he produce a feeble whisper. He was given rectal feeds. Three days later the wound in the neck became septic, discharging pus freely and the stitches gave way and had to be removed. The patient was then fed through the neck wound. On the 19th January, 1936, nasal feeding was tried and proved to be satisfactory. The patient gave trouble, refused to accept food and tried to run away.

(For the above notes I am grateful to my assistant at Shwegyin, Dr. Hans Raj.)

The patient was transferred to the Headquarters civil hospital, Toungoo, on the 22nd January. The journey took about 10 hours.

On admission the wounds were described as follows:—

'1. One septic incised wound on the upper part of the neck extending from one angle of the jaw to the other cutting through the throat above larynx and oesophagus partially.

2. Incised wound at root of penis, one inch broad'. The patient was in an extreme state of emaciation due to starvation. The first photograph was taken after the patient had been in hospital for about ten days. He was too weak to sit up and could not even hold his head up. Physical examination was otherwise

negative. The following structures could be identified as having been cut—skin, platysma, suprathyroid muscles, thyro-hyoid membrane, part of sterno-mastoids and epiglottis. The posterior wall of the pharynx was exposed and the retraction of the skin had exposed the upper part of the thyroid cartilage.

The patient was fed through the wound with a tube and funnel and seemed to be perpetually hungry. Four pints of milk with eggs, sugar and glucose were given

each day. The wound became quite clean and the patient's general condition improved day by day. On 20th February the wound was stitched up under local anæsthesia; the base of the epiglottis was also pulled down and stitched into place as I imagined that this

procedure would be necessary for the proper performance of swallowing. The head was kept hyperflexed. The patient received food surreptitiously from neighbours and developed a cough which burst several of the sutures. As bleeding occurred from the raw areas, the other stitches had to be removed to facilitate pressure on bleeding points by the dressing. Having read in the *Medical Annual* of 1928 and of 1929 notes on treatment of gaping wounds by skin traction and adhesive strapping, I decided to try the method in this case. The edges of the wound were kept approximated by sticking plaster and bandage and the patient was enjoined to keep the head flexed and placed in the propped-up position. He was fed through the nose quite easily. His weight and general condition improved steadily and the wound also became smaller and smaller. By 2nd April, only a small hole was left in place of the previous gaping wound. This is shown quite clearly in the second photograph which was taken about this time. He was discharged from the hospital on the 14th May with only a small scar left to indicate the wound.

Commentary

More on account of worry due to precarious livelihood than to any other cause, the patient must have developed suicidal mania, and mutilated himself and attempted to commit suicide by cutting his own throat. It was sheer good luck that the big vessels in the neck escaped division. This might be explained by the fact that in his frenzy in attempting to make a good job of it, he hyperextended his neck, thereby pushing the big vessels posteriorly in the level of the wound. My idea that anatomical result should be perfect to enable the swallowing act to be normal was proved to be wrong because in spite of the fact that the cut ends of the epiglottis were not united swallowing was normal and no solid or liquid food entered the trachea.

The ease illustrates the utility of approximating the edges of a wide wound by means of plaster or other means to promote healing.

SPONTANEOUS SUBARACHNOID HÆMORRHAGE

By C. K. MENON, M.B., B.S.

Honorary Assistant Surgeon, Government Headquarters Hospital, Calicut

PATIENT, male, aged 22 years, was admitted into the Government Headquarters Hospital, Calicut, on 20th September, 1938, at 10-30 a.m. with severe headache and restlessness.

The history was that on 17th September at about 8-30 p.m. the headache started suddenly and became intense in a few minutes. He vomited the food he had taken a few minutes previously. A doctor was sent for who gave an injection. The patient's condition was so upsetting that within a few minutes another doctor was called in and gave another injection without any benefit. What was injected is not known. The patient continued in this state of agonizing headache till next morning, when yet another doctor was called in under whose care he remained for two days with no improvement. On the 20th morning he was admitted into the hospital.

Previous history.—Four months ago he had a fall from a height of about 20 feet hitting the left side of his head on the ground. He was unconscious for ten days and when he recovered he had lost the vision of his left eye with no other sequelæ.

On admission, temperature 97.4°F., pulse 54, blood pressure 110/84. Patient was confused, pupils dilated.

Motor system—power fair, no atrophy, tone normal. Reflexes—deep—no response; superficial—abdominal absent.

Sphincters—normal.

Sensation—normal.

Kernig's sign elicited; stiffness of neck present but no retraction.

Other systems—normal.

Urine—1005, acid, no albumin, no sugar.

Ophthalmic surgeon's report:—The right eye was homotropinized and examination did not show any peculiar feature. No papilloedema, pre-retinal and sub-hyaloid hæmorrhage absent.

Ptosis with slight exophthalmos present.

The acute onset with subsequent meningeal irritation led me to do a diagnostic lumbar puncture when blood was found intimately mixed with the cerebro-spinal fluid. Accidental contamination was ruled out by allowing the fluid to stand for a few hours when it was found that there was no clotting but only a little sediment with a column of clear yellow fluid above. A diagnosis of spontaneous sub-arachnoid hæmorrhage was made.

Subsequent progress. The lumbar puncture relieved the headache and the patient felt better.

21st September. Restless and complaining towards the evening. Temperature 101°F., pulse 96, respiration 26 per minute. Morphia was given and a fair night passed.

22nd September. Still complaining but lumbar puncture was not done for fear of removing too much fluid and continuing the hæmorrhage. Morphia relieved the patient. Temperature 100°F., pulse 70, respiration 24 per minute.

23rd September. Lumbar puncture was done and 20 c.cm. of blood-stained fluid withdrawn. It was under pressure but bleeding was being arrested as shown by the lighter colour of the fluid. This puncture seemed to have a better effect than the first. Temperature 99°F., pulse 61, respiration 24 per minute. Morphia was not given.

24th September. Patient better though still complaining of pain. Morphia was given at night. Temperature 99°F., pulse 80, respiration 24 per minute.

From then onwards he improved steadily though still complaining of headache and pain in the right eye.

3rd October. Another lumbar puncture was done and this time though the fluid was still under pressure it was almost clear to the naked eye.

He was discharged on 6th October at his request, with practically no pain.

An important feature of the case in the later stages of the illness was the mental symptoms with loquaciousness.

I report this case so that the definite clinical entity of subarachnoid-hæmorrhage may be more readily recognized by the general practitioner as a fairly common occurrence. The condition, if recognized, is easily handled and if not diagnosed is often wrongly treated.

One difficulty in such cases is to decide how often lumbar puncture is to be repeated. In the early stages when bleeding is going on, it should only be done for diagnosis and to prevent death from medullary compression. In the later stages only sufficient fluid should be taken to relieve the headache.

The commonest causes are :—

- (1) rupture of an aneurysm,
- (2) unexplained sudden rupture without aneurysm formation,
- (3) hæmorrhage from a tumour which impinges upon the cortex or upon the ventricular wall,

(4) bleeding diseases,

(5) trauma.

It is probable that the trauma he sustained 4 months before caused this condition.

My thanks are due to Major S. T. Davies, I.M.S., Superintendent of the Government Headquarters Hospital, Calicut, for his advice and permission to publish these notes.

[Attention is directed to a note by Dr. R. N. Chaudhuri on this subject in our August number of 1938 (p. 466).—EDITOR, I. M. G.]

A CASE OF ALKAPTONURIA ASSOCIATED WITH OCHRONOSIS AND PURPURIC RASHES

By B. B. BHATIA, M.D., M.R.C.P. (Lond.)

Physician, King George's Hospital, Lucknow

ALKAPTONURIA is a rare disorder; alkaptonuria associated with ochronosis being still rarer, there seems enough justification for publishing the following case :—

A male, aged 60 years, non-vegetarian, farmer, was admitted into King George's Hospital on 20th September, 1938, with vague pains all over the body, pain

Photograph shows swelling of the knee-joints, scars of old ulcers on knees and shins, patchy pigmentation of palms, brown coloration of the toe nails.

and limitation of movements in the knee-joints and inter-phalangeal joints. The duration of these complaints was ten years; for the first six or seven years he was able to carry on with his work, but later on had to give it up and has been bedridden for the last two

years. There was nothing of importance in the past or family history.

On examination it was discovered that the patient was covered with cutaneous and subcutaneous hæmorrhages. At two or three places in the hands and legs, the hæmorrhagic patches had gone on to ulceration. Both the legs were covered with scars which, according to the patient, were due to ulcerations following previous hæmorrhages. The palms of the hands were very much thickened and had patches of peculiar slaty-blue pigmentation, the hollows of the ears also presented similar coloration. Knuckles were pigmented and the nails were of uniform brown colour. There were a few brown flecks on either side of the cornea in both eyes. Both knee-joints were swollen, with marked creaky sensation on movement, which was restricted. No evidence of fluid in the synovial sacks. There was slight swelling and restriction of movement in all the inter-phalangeal joints. The rest of the joints appeared normal, nor was there any history of their having been involved in the past. There was some hardening and pain in the calf muscles.

The peculiar distribution of pigmentation and arthritis suggested the possibility of ochronosis. This was confirmed by the examination of the urine, which revealed changes typical of alkaptonuria.

Urine examination.—Fresh specimen was straw colour, specific gravity, 1020, no albumin, reduction of Fehling's solution + +, no casts, no bile pigments or salts. On addition of strong alkalis, colour changed to dark brown. On addition of dilute ferric chloride transient blue coloration was produced. An hour old specimen presented dark brown colour.

Blood examinations.—

Wassermann reaction—completely negative.

Bleeding time—2 minutes 20 seconds.

Coagulation time—2 minutes.

Blood platelets—310,000 per c.mm.

Blood calcium—10 mgm. per 100 c.cm.

Red blood cells—3,670,000 per c.mm.

White blood cells—15,810 per c.mm.

Differential—

Polymorphonuclears—74 per cent.

Lymphocytes—23 per cent.

Eosinophiles—3 per cent.

Hæmoglobin—65 per cent.

X-ray report.—Radiologically scurvy not indicated. Calcified arteries present on both sides. At the knee-joint, inter-articular space considerably narrowed, with destruction of articular cartilage.

Smear after prostatic massage. Negative for gonococci.

Discussion

The changes found in the urine were typical of alkaptonuria. Probably the patient had this disorder from his birth, as he gave the history that, ever since his childhood, he had noticed that drops of urine left dark stains in his clothes. No family history of such disorder in other members was obtained. One grown-up son of the patient, who happened to be in the wards at the same time suffering from rheumatic heart disease, showed no changes in his urine. Staining of the cartilages of the ears, cutaneous and sub-cutaneous staining evident on his knuckles and palms and its peculiar slaty-blue colour were typical of ochronosis. There was no history of any application of carbolic acid to any of his ulcers. Thus the cause of his ochronosis was the presence of long-standing

disorder of metabolism (alkaptonuria). The patient had suffered from occasional dysuria for several years, but the main symptoms which brought him to the hospital—vague pains all over the body, and arthritic condition of the knee, and inter-phalangeal joints—were of ten years' duration and were getting gradually worse. Staining of the tissues and purpuric rashes appeared at the same time. It thus seems reasonable to assume that all these changes followed the deposition of homogentistic acid pigment in the tissues. Staining and arthritic changes have been previously described, but, from the literature available in Lucknow, I could find no records of purpuric rashes occurring in this disease. All the well-known causes of chronic hæmorrhages were thought of, but none fitted with the clinical picture. Vitamin-C content of his urine was normal. The various blood tests, such as bleeding time, coagulation time, platelet count and blood calcium, were within normal limits. The only positive test was the capillary resistance test of Hess; armlet of blood-pressure instrument placed round the upper arm for five minutes at pressure of 110 mm. of mercury midway between the systolic and diastolic figure produced a crop of hæmorrhages on the forearm. This test implied that changes in vascular endothelium were mostly responsible for his hæmorrhages.

Could these changes have been brought about by homogentistic acid?

LIQUOR ARSENICALIS IN THE TREATMENT OF CHOREA

By K. G. RAMABHADRAN

Madura

LEONARD WILLIAMS observed on pages 356-8 of his book *Minor Maladies and Their Treatment*, 'The treatment of chorea by large doses of arsenic was invented by an unqualified practitioner, who, on his death-bed, disclosed the secret of his success to Dr. Murray'. The secret was this: 'Fowler's solution, in 15 to 20 drops doses, might generally be given to children from 10 years old upwards for a few days without disturbing the stomach and that so given it was an almost infallible cure for chorea within a week'. Dr. Murray's own observations confirmed the value of the drug so given, but he insists that two rules should be observed. The one is that the minimum dose should be 15 drops of Fowler's solution, the other that the treatment should not be continued for more than one week.

A trial extending over several years enables me to speak with some assurance as to the efficacy of this method. It does good in the large majority of cases; in some instances it is brilliantly successful, and in a few cases it fails completely. But I do not agree that it is essential that the treatment should be stopped on the eighth day. I have, indeed, found that to do

this, is often to lay down the weapon just as it commences to be operative; that it is in fact during the second week of large doses that the symptoms yield. It is of course necessary to warn the parents' attention against signs of intolerance during this second week. I have found, further, that absolute rest in bed, combined with a diet from which fish, flesh and fowl are rigidly excluded, greatly increases the prospect of cure by this, or by any other method. Finally, I have found that the addition to the mixture of large doses (20 minims to 1 drachm or more) of liquid extract of ergot, as suggested by Dr. Eustace Smith, notably increases the percentage of cures.

Case I, August 1936.—A girl, aged 12 years. She was very intelligent and she was overworked in the home. Jerks were very severe, and in almost the whole of the body. She had sleepless nights. Luminal, veronal and allied drugs had practically no effect. Injection of morphine had to be given to obtain a few hours' rest. The following mixture was then tried:—

R Liquoris arsenicalis	℥ 15
Potassii bromidi	gr. 30
Syrupi aurantii	oz. 3
Tinctura cardamomis co.	℥ 30
Aque chloroformi	oz. 3

On the second day liquor arsenicalis was increased to 20 minims and on the third to 30 minims at which it was kept for a week. Some improvement in the patient's condition was noticeable and the mixture was continued for another five days, and then stopped. The girl improved rapidly and there has been no recurrence since.

Case II, November 1936. A boy, aged 11 years, son of a clerk. He was an intelligent boy and was studying away from his parents under the care of relatives who are alleged to have persistently ill-treated him. The patient was brought down by his parents a few days after the onset of the attack. There was partial paresis in the right upper and lower extremities and the symptoms were typical of a severe attack of chorea. The tonsils were slightly inflamed. A purgative followed by the mixture with 30 minims of liquor arsenicalis and bromides were given. This was continued for 10 days and the symptoms lessened considerably. After an interval of 10 days the same mixture was resumed, this time with the addition of a full dose of extract of ergot. The boy got much better. Slight weakness in the extremities was remedied by the administration of general tonics for a period of two months. There has been no recurrence since.

Case III, September 1938. A girl, aged 10 years. The patient was sleeping in the afternoon when she was suddenly awakened by her mother. As she got up her right hand began to shake violently. Weakness in the right leg developed and there were twitchings on the right side of the face. On examination the pulse was rapid (105 per minute) and the temperature was normal. There was a systolic murmur with its maximum intensity in the pulmonary area.

About four years previously the child had had typhoid fever lasting for 22 days. Since then once every year during the rainy season she developed slight breathlessness and cough accompanied by slight rise in temperature and pain in the joints. In each case the symptoms used to last only for three days and the child got completely better. Since last year's (1937) attack she used often to complain of pain in the left side of the chest and back and neuralgia in the head. The child is very intelligent, and is top of her class.

Liquor arsenicalis, 24 minims a day, was started along with bromides and tincture of digitalis. The patient was put to bed and given plenty of glucose. Luminal was given for sleep. On the third day the

dose of liquor arsenicalis was increased to 30 minims. Tincture digitalis was stopped after a week, but the liquor arsenicalis was continued for 15 days. The child began to improve from the third day and is now completely recovered. The pulse rate has come down to 80 and the murmur in the heart has disappeared.

HYDROPHOBIA FROM A MONGOOSE BITE

By B. M. ROY, L.M.F.

Assistant Medical Officer, Nonaipara Tea Estate,
Dimakuchi, Assam

On 26th September, 1937, I was called to see a Nepali boy, aged 12 years, in the Bhutan border who was suffering from fever with delirium.

On examination I found the temperature 103.4°F.; pulse and respiration in proportion.

Lungs—no adventitious sound.

Liver—normal.

Spleen—2 inches below costal margin.

Urine—high coloured.

Blood examination—*Plasmodium falciparum* found.

Aldehyde test negative.

Hæmoglobin—about 50 per cent.

The father of the patient said that the boy had been delirious the whole night.

The usual malaria treatment with a purgative was given and a cold douche over the head was ordered if and when the temperature rose.

Next morning the temperature was 102.8°F. Bowels acted well, but some new symptoms had developed, painful spasm of pharynx while attempting to swallow anything. The throat was examined but nothing noticed. The patient was kept under careful observation and in the afternoon the following symptoms developed: clonic spasm of the respiratory and neck muscles, sense of constriction of the fauces, swallowing even a little water was difficult, frightened appearance, but could answer questions clearly.

28th September.—The condition was somewhat aggravated. A peculiar sound was emitted when he wanted to expectorate. Swallowing any food was impossible, even the sound of any liquid gave him a convulsion. These signs led me to enquire if the boy had ever been bitten by a dog. The father said no, but about a month before while working with him cutting jungle near their house, the boy was bitten in the hand by a wild mongoose. The animal was then killed by the father and the four teeth marks in the boy's hand were dressed with pulverized turmeric, which resulted in quick healing without any visible scar, within a few days.

29th September.—The face was expressionless, signs of paralysis of lower jaw, irregular breathing, excessive secretion of saliva which he could not expel and which was dribbling from the angle of the mouth. He could not answer any questions and both pupils were widely dilated.

The patient died at about 2 a.m. in the morning with complete paralysis.

Conclusion.—It is I think a typical picture of hydrophobia.

Can a mongoose be responsible for hydrophobia?*

I am grateful to Dr. E. Burke for his permission to send this case note for publication.

*[Note.—We refer our readers and the contributor of this note to Vol. LXVII, p. 451, and Vol. LXVIII, p. 20, of the Gazette in which details of 10 cases of rabies from mongoose bites are recorded.—Editor, I. M. G.]

MARCH

THE VITAMINS: NICOTINIC ACID AND PELLAGRA

Writing contemporary history is always an exceedingly difficult task; the history of scientific advances provides no exception to this general rule. For example, who first discovered vitamins? There is of course no satisfactory answer to such a question, and, in giving the names of half a dozen workers in whose brains the ideas that have grown into the extensive, though still far from complete, knowledge that we now enjoy first germinated, we are conscious that there are many others whose contributions though less spectacular were equally important. Discoveries are no longer made by an isolated worker behind locked doors, but ideas are passed rapidly from scientist to scientist, each adds his quota, and thus knowledge, which a hundred years ago would have taken several decades to develop, now takes only as many months. A quarter of a century ago our total knowledge on the vitamins could have been written on a postcard, whereas to-day 'a concise review of modern knowledge about vitamins' appears not in one but in seven volumes.

In order to evaluate the contributions of different workers in this field, it is necessary to appreciate that there are certain definite stages in the development of our knowledge on vitamins. Firstly, the existence of certain diseases, scurvy, beri-beri and rickets, was observed and it was noted they were associated with obvious defects in the diet of the sufferers. It was then found that these diseases were associated with the absence from the diet of certain specific food substances, very small quantities of which added to the diet would prevent and even cure these diseases, which were therefore called 'dietary deficiency diseases'. In the next stage it was shown that life—of animals including man—cannot be maintained on a basic diet of purified protein, fat, carbohydrate, minerals and water, but that the addition of minute quantities of a number of other substances is essential; the source of these substances and certain crude facts regarding their general chemical and physical properties, e.g., rate of oxidation, water solubility and heat stability, were known, but nothing more regarding their nature; this is evident from the first name given to them, 'vitamines', afterwards changed to 'vitamins' to mark the recognition of the mistake, when it was discovered that they were not 'amines'. The next was a stage of multiplication of these vital substances when the original four were split up into the dozen or more of the present day. And the final stage is

the chemical identification and synthesis of these vitamins; this stage is of course not yet complete.

One realizes that if in each of the early stages of the development of the subject some half dozen or so workers played important parts, then for the later stages the number will have to be raised to hundreds, and before the picture is anything like complete to thousands. Out of this galaxy the historian of the distant future will no doubt pick some special names to honour, and at least he will not be hurting the feelings of any living scientist or his immediate associates, but we doubt if he will be getting any nearer the truth than we could hope to do to-day.

To-day it is the chemist who occupies the centre of the vitamin research field, and during the last few years remarkable advances have been made in the chemical identification of the vitamins. There are now at least nine vitamins, or pre-vitamins, of which the exact chemical formula is known; these include vitamin A and carotene, ascorbic acid, two vitamins D, vitamin E, vitamin B₁, and of the vitamin B₂ complex, lactoflavin and finally nicotinic acid. The importance of this exact knowledge is evident, even if we leave out of consideration the fact that identification is obviously an essential step in the synthesis of these substances.

Nicotinic acid, the most recent recruit to the vitamins whose chemical formula is known, provides a very good example. Many theories have been put forward regarding the cause of pellagra and, although the general opinion has for some time been veering towards Goldberger's pellagra-preventing (P-P) factor deficiency theory, the subject was still a controversial one. Now, since nicotinic acid has been identified as the P-P factor, within a year the whole aspect of the subject seems to have changed, and the part played by this substance in preventing and curing the symptoms of pellagra is so well understood that response to nicotinic acid is now being used as a therapeutic test, and symptoms that do not respond to this treatment are considered not to be part of the true pellagra syndrome.

In September 1937, Elvehjem and his co-workers reported that nicotinic acid cured black-tongue, a condition in dogs that previous work had shown to be analogous to pellagra in man, and before the end of the year three independent groups of workers, including Harris in Cambridge, had reported good results in human pellagra with nicotinic acid, even when the patients were allowed to continue their pellagra-producing diet. The next twelve months produced a score or more convincing reports on the therapeutic value of nicotinic acid and seldom has any therapeutic measure received such a consistently good 'press'. A few warning notes have been sounded, but no serious results, even from gross overdosage, have been reported, and its therapeutic limitations seem only to be encountered beyond the true pellagra syndrome.

One observer has killed a dog by giving it 2 grammes of nicotinic acid daily for 13 days, and others have produced 'very disagreeable symptoms' in healthy students by giving them a gramme a day for ten days. However, as the maximum therapeutic dose recommended is about 500 mgm., these dosage limitations are unimportant. The general opinion is that a dose of 200 to 300 milligrammes by mouth, or of 100 mgm. parenterally, is usually adequate.

Another point raised is that vitamin B₁ is a necessary addition when neuritis is a prominent symptom, and many workers add that in order to ensure permanence of cure a good protein diet is advisable.

Few contributions of the biochemist to the study of the vitamins have had such an immediate and spectacular clinical reaction, as the isolation and chemical identification of the pellagra-preventing factor.

THE YELLOW FEVER POSITION*

By SIR ALEXANDER J. H. RUSSELL

COLONEL, I.M.S.

Public Health Commissioner with the Government of India, New Delhi

ON two previous occasions, my predecessor gave at these Conferences a brief description of the yellow fever position in so far as it affected India. Our new knowledge of that disease, the great development of air traffic which has occurred during the past few years and the certainty that still wider developments will be made in the near future seemed to me to justify the presentation to you of a picture of recent events and of the precautions which are now being taken.

A most welcome feature of more recent times has been the wider recognition of the danger of the spread of yellow fever to countries hitherto free from that disease. The change of outlook among certain delegates to the Office International has been most striking, and this I attribute in great part to the stiff attitude adopted from the first by the delegates from India. I have been called an 'enfant terrible' and an obstructionist in at least one meeting of the 'Office', but we have persisted in our efforts and there is now general agreement with the Indian point of view. Moreover, civil aviation departments and air companies in general, after a readily understandable hesitation, have now come to a fuller appreciation of the dangers to public health implicit in rapid air transport and these organizations are now working in friendly co-operation with public health departments in every part of the world in the effort to prevent the spread of disease by infected persons and insects. The Rockefeller Foundation has once more placed the whole world under a deep debt of gratitude by its magnificent work not only in respect of extension of our knowledge of the epidemiology of yellow fever but also in organizing systematic preventive campaigns in endemic areas.

Some of the new facts which have come to light in recent years are of great interest and importance. For instance, it has been possible to reproduce in *Macacus rhesus* the signs and symptoms of human cases and so to make an intensive study of the disease in experimental animals. It has also been proved that microscopic sections of the liver tissue of a yellow fever case present characteristic signs by which a diagnosis can be made; by means of a simple instrument known as the viscerotome portions of liver tissue can be obtained without carrying out a detailed post-mortem examination.

Further it is now possible by the elaboration of what is called the mouse-protection test to determine whether or not any given person has previously had an attack of yellow fever. The extended application of the mouse-protection test, using the sera of persons living in suspected regions, has made it possible to map out the boundaries of endemic areas and of what are known as the 'silent' areas.

Finally, experimentation over a period of years has resulted in the elaboration of a technique which permits of the production of a potent protective vaccine—one which in its latest form does not produce the jaundice and other toxic symptoms which followed injection of the earlier types of vaccine.

From field and laboratory studies in America and Africa, our ideas of the epidemiology of yellow fever have undergone a remarkable transformation. Yellow fever was until recently believed to be solely an urban and coastal disease, its incidence being thought to be dependent on the presence of *Aedes aegypti*, which was the known transmitting agent. The disease was diagnosed from what was assumed to be a classical syndrome and the absence of typical cases was interpreted as meaning freedom from infection. Studies of the viscerotomy liver sections taken from all persons dying from fevers of over ten days' duration and the application of mouse-protection tests have established that 'definite and recognized clinical cases only form a very small proportion of the cases of yellow fever' occurring in an endemic area. It is the mild unrecognized cases which keep infection

* Delivered at the 16th All-India Medical Research Workers Conference, New Delhi, December 1938.

going on, because they frequently remain undetected, they therefore constitute a grave danger in respect of spread of the disease.

South America

In South America, the urban and coastal type of the disease was that which was the object of vigorous preventive measures for many years.

Within the last two to three years, however, a new type known as jungle yellow fever has been found to exist. This type differs in many respects from that originally described and Dr. Soper, the Rockefeller Foundation authority on yellow fever, considers it to be the older and more permanent form of the disease. Dr. Soper describes it as follows:—

‘Urban and rural *ægypti*-transmitted yellow fever is generally acquired indoors, tends to affect non-immunes of all ages, spreads along the lines of human travel, and is easily controlled by reduction of the density of the vector. Jungle yellow fever, on the other hand, is acquired in or near the forest during working hours by those whose occupation takes them to the woods and does not affect other members of the household. The infection of men is apparently accidental, occurring in the course of some cycle of infection of which man is not an essential part. Recently forest mosquitoes (*A. leucocelænus*, *Hæmagogus capricorni* and species of *sabathines*) have been captured naturally infected and furthermore there is some evidence that certain monkeys commonly become infected; but it is difficult to fit all the observed facts into a simple mosquito-monkey-mosquito cycle of which man's infection is but an accidental offshoot’.

Whereas, therefore, yellow fever was previously considered to be confined to coastal regions, it is now known to be widespread through vast inland areas of the South American continent and at the moment the problem of its eradication seems outside the bounds of practicability.

Africa

In Africa, it had also been long believed that the endemic yellow fever areas were relatively restricted. The surveys made by using the mouse-protection test have revealed that the disease must have prevailed over much wider tracts of that continent and, in fact, the eastern boundaries of what have been termed the ‘silent’ areas are gradually being extended more and more eastwards as further surveys are carried out. It may well be that these areas are ‘silent’ only—because of the absence of medical aid and the lack of facilities for carrying out the necessary laboratory and animal tests.

From the point of view of India and the Far East, the African endemic and ‘silent’ areas must be looked upon with equal suspicion and in face of stubborn opposition we have persistently maintained that the same preventive measures must be applied in respect of both.

The map of Africa [not reproduced] shows the various spots where cases of yellow fever have recently been found and it also indicates the known ‘silent’ areas. The main endemic foci are of course in West Africa, but within recent months, two very suspicious cases have been recorded as far east as Malakal, in the Anglo-Egyptian Sudan, where lies an aerodrome on the Cape to Cairo air route.

On the same map has also been drawn the main air routes in the African continent, but of course these are being rapidly extended and it is not too easy to keep the map up to date. The main British route runs from Alexandria to Cape Town and the West African line from Lagos and Kano crosses through a well-known endemic area before joining the main route at Khartoum. During my visit to Egypt in March of this year, by the courtesy of the Egyptian Government and of the International Sanitary and Maritime Quarantine Board of Egypt, I was given the opportunity of inspecting the aerodromes at Alexandria and at Cairo and of seeing the precautionary measures taken by the health authorities at these important airports.

For the last two to three years, the Egyptian Quarantine Board has been carrying out all necessary measures, including disinsectization of aircraft with Pyrocid 20, for the prevention of spread of yellow fever to the north and east. By arrangement with the Government of India, too, the Board agreed to issue certificates of disinsectization to all aircraft coming from infected or suspected yellow fever areas which were proceeding to India and in addition the Director of the Board sends a telegraphic warning to the Airport Health Officer, Karachi, in respect of any passenger proceeding to India by air within nine days of having left an infected or suspected yellow fever area. In return we send telegraphic information in respect of any suspected passenger leaving a cholera- or smallpox-infected area in India by air for the West.

With the opening of the Lagos-Khartoum air route in 1937, it was obvious that the danger to India was enhanced unless stringent precautions were taken and that Khartoum had become the key position for the sanitary control of north-bound air traffic.

During a visit I paid to Khartoum at the end of March, I was able to discuss the whole question with the Anglo-Egyptian Sudan Government and their Director of Medical Services. The Sudanese authorities are very much alive to the necessity for taking all possible precautions against a yellow fever invasion and the measures taken there, in my opinion, provide a valuable and effective barrier to the extension of infection to other countries including Egypt, Iraq and India. I was informed that the *Aedes ægypti* had never been found in Khartoum, and that every step was in force to prevent its introduction there, while an intensive anti-*Aedes* campaign was being carried out in every large centre in the Sudan.

It was fortunate that my visit to Khartoum coincided with the arrival of a Lagos air liner bringing ten passengers across the African continent. The Sudan Government has made arrangements with the West African Governments under which no air passenger is permitted to leave those countries for Khartoum and Egypt unless he has resided in a yellow-fever-free area for at least six days immediately prior to embarkation and each passenger must be in possession of a certificate to this effect signed by the Airport Health Officer of the port of embarkation. On arrival at Khartoum, each passenger must produce this certificate, as I saw for myself, and unless it is presented, the passenger is not allowed to proceed but is detained under surveillance for six days. A few days before my visit, an English banker, who had arrived at Khartoum from Kano without the certificate, was detained for six days before he was allowed to proceed to Cairo and Europe. After the passengers had disembarked and before the removal of baggage, mails or passengers' effects, every compartment of the machine was thoroughly fumigated with Pyrocid 20 and, having seen the methods adopted, I felt convinced that no mosquito could possibly escape with her life. The Airport Health Officer at Cairo also informed me that if, on interrogation, a passenger was found to be on his way to India, he was not allowed to proceed unless he was in possession of the necessary certificate.

Whilst, however, we may be assured that suitable preventive measures are in force against the danger of the spread of yellow fever to India, it must be remembered that no insurmountable defensive barrier has been built up. The change from land planes to sea planes has rendered control of aerodromes much more difficult. It will be obvious that a land aerodrome can be kept free from *Aedes* much more easily than a marine airport. Moreover, private aeroplanes will without doubt become an increasingly important factor as these machines have frequently no definite route and may cross and re-cross infected areas without the cognizance of any health authority. For example, a private air line, with headquarters at Aden, is now operating between Massowa, Port Sudan, Djibouti and Baghdad, the machines landing at any convenient aerodrome. I may add that the late Miss Amelia Earheart during her ill-fated world flight made no call at Khartoum on her way across Africa and so escaped detention there after her flight across the yellow fever infected areas of West and Central Africa. Private aeroplanes may also intentionally or unintentionally enter India through airports other than Karachi, the authorized port of entry, and thus land in a place which is not equipped to take the necessary precautionary measures. Finally, although as far as is at present known, the most easterly infected region in Africa is Malakal in the Anglo-Egyptian Sudan, any spread of infection to the ports on the east coast of Africa

would be attended with very serious consequences because, as Dr. Soper has said, 'every boat headed for India would become a definite threat'.

India

As regards this country, considerable progress has been made in the measures designed to prevent the introduction of yellow fever. In 1936, the Government of India issued regulations which prohibit entry to any aeroplane which has started from or alighted in an infected or suspected area within the previous nine days. The same rule applies to any person who has started from or alighted in an infected or suspected area, except at an anti-amaryl aerodrome, within the previous nine days, unless he has been protected by satisfactory inoculation or by a previous attack of the disease. The Aerial Navigation Sanitary Convention lays down six days as the period of prohibition of entry and considerable criticism was made of India's insistence on nine days, but there are good reasons for this extension and we cannot afford to take any risks so long as we have free breeding of *Stegomyia* all over India, a non-immune human population and a vast reservoir of monkeys now known to be susceptible of carrying the disease.

Karachi is the airport of entry to India for all air traffic coming from the West. The aerodrome there may now be classed as 'anti-amaryl' according to the Convention, as suitable steps have been taken to provide the airport with a health staff and to keep the *Aedes* index at a minimum. Adequate provision has also been made for the segregation of suspected or infected persons arriving by air, a 12-bedded mosquito-proofed isolation hospital having been built on the outskirts of the aerodrome. A mosquito-proofed ambulance is also available for the transfer to this hospital of suspected persons arriving at the marine airport.

In regard to protection by inoculation with the yellow fever vaccine, arrangements have been made with the Wellcome Research Laboratory in London to give training in the method of inoculation to public health and medical research department officers who may be on leave in England. Those who decide to take this training should either apply to the Public Health Commissioner or in London to the High Commissioner for India.

An emergency supply of the vaccine is also being kept at the Haffkine Institute, Bombay, whilst arrangements are being made under which at the Wellcome Research Laboratory in London 400 doses are earmarked for immediate despatch to India. It would be of advantage to India in general and to the medical profession in particular, if medical officers proceeding to England would use the opportunities afforded to learn the method of inoculation and to have themselves protected. If yellow fever should break out here, there will be an immediate demand for a large medical and preventive staff and it would

of course be to their own advantage to be immune to the disease.

Considerable experience has been gained in the use of the yellow fever vaccine. In a recent address to the Royal Society of Tropical Medicine and Hygiene in London, Dr. Soper reported, in connection with the preventive campaign against jungle yellow fever, that as individual immunization of the exposed population alone offered any reasonable hope of prevention 'during the first nine months of 1938 more than 800,000 persons have been vaccinated with entirely satisfactory results and without serious complications of any kind'.

Finally, the question of preventing the spread of the disease by the carriage of infected mosquitoes in aircraft is of the utmost importance. The fumigation of all aircraft coming from suspected or infected areas has been in general practice for the last two to three years. Various fumigants have been used by different authorities, that in use in India and in Egypt being a substance known as Pyroicide 20, which consists of a pyrethrum base diluted with kerosene. Every compartment of the aircraft is freely sprayed with the fumigant before any unloading of baggage, mails, etc., is allowed, so that any mosquitoes may be destroyed. Because of possible danger from fire following the use of a fluid containing kerosene oil, Imperial Airways have recently been experimenting with a new fumigant called 'deskito' which is a watery base preparation of pyrethrum. With this substance it is proposed to carry out the process of fumigation in the air immediately the aeroplane takes off and this method has the obvious advantage that mosquitoes which have gained an entry just prior to departure from an infected or suspected area will be destroyed at once, before they have the opportunity of biting passengers or crew. The use of a thoroughly efficient disinfectant is a matter of great importance to India and we have consistently taken up the attitude that no fumigant will be accepted until it has been submitted to rigorous tests by the Malaria Institute of India.

Even from these somewhat sketchy remarks, you will have appreciated that the Government of India are acutely alive to the danger of the introduction of yellow fever into this country and that, in the light of existing knowledge of the disease, we have taken every possible step to ensure that such a catastrophe may be avoided. The situation in East Africa, however, is one which demands continued vigilance and I think you may be certain that the Public Health Department of the Government of India will continue to maintain its present watchful and critical attitude.

List of areas in Africa regarded as infected with yellow fever or suspected of being infected with yellow fever:—Angola, Anglo-Egyptian Sudan, South of Khartoum, Belgian Congo,

DIET AND PEPTIC ULCER*

By M. NARASIMHA RAO, M.B., B.S.
Formerly Research Fellow in Medicine,
Andhra University, Waltair

THIS short note is not a study of the pathology of the problem, but rather a study of the wider aspects of the subject. I have attempted to show that diet plays a prominent part in the ætiology of peptic ulcer in India.

By peptic ulcer, in the following lines, it is meant to represent, not the acute ulcer or the erosion, but the entirely different pathological entity, the *chronic* ulcer, that is commonly found at the following sites of the gastro-intestinal tract in man:—

- (i) the lesser curvature of the stomach,
- (ii) the first and second parts of the duodenum and, rarely,
- (iii) in the case of post-operative gastro-jejunostomy, the first part of the jejunum.

Peptic ulcer is a far more common disease in the south than in the north of India; it is in fact supposed to be 58 times more common (McCarri-

son, 1921). The following graph I (Mc Carrison, 1936) brings out this fact very vividly, and represents the number of peptic ulcer cases treated in hospitals per thousand of population.

GRAPH I

surgical side were cases of peptic ulcer (Rao, 1938b), the corresponding figure for Calcutta was only 1.54 per cent.

* Paper read before the Public Health Society on the 4th November, 1938.

(Continued from previous column)

Cameroons, Dahomey, French Equatorial Africa, French Guinea, French West Africa, Gambia, Gold Coast Colony, Ivory Coast, Kenya Colony, Liberia, Nigeria, Senegal, Sierra Leone, Tanganyika Territory, Togoland, Uganda, Upper Volta Territory.

One can think of various factors for this marked difference and I shall discuss here some of the more important ones.

It is believed by some Australian workers that climatic conditions may be responsible for the causation of the disease. However, in this case, meteorological conditions cannot be responsible, for in South India the incidence of ulcer is almost equally high in all parts in varying climatic conditions, in Malabar and the Northern Circars, in Coonoor and Madras. Similarly, comparing the meteorological conditions prevalent in North and South India, it can be shown that the climatic condition is not an important aetiological factor.

Next the racial factor may be considered. In Travancore and the Northern Circars, a group of four northernmost districts of the Madras Presidency (Rao, 1938b), the disease is more prevalent in the lower castes. And the lower castes in Bengal and North as well as in South India chiefly consist of the orientals and the aboriginals. And the racial distinctions between Bengal and South India, if any, is only in the Dinaric and Armenoid strains and not in the orientals and the aboriginals. Hence, one does not find in the South Indians a racial predilection either.

Dietetically, it is more complex on account of various factors.

That the diet to a large extent is responsible for the greater incidence of ulcer in South India has been suggested by McCarrison, and he attributed it to the difference in the nutritive quality of the diet of the people. He substantiates his statement by experimental evidence in which groups of rats fed on diets corresponding to those used by Sikhs and the poorer classes of Madras, respectively, for 700 days showed on post-mortem examination that the first group had no peptic ulcer and the second group had it to the extent of 11 per cent. Even among the South Indian dietaries, predisposition to ulcer formation varies with the dietetic variation in different parts. Thus McCarrison is of opinion that the diet used by the lower classes in Travancore predisposes to ulcer formation more than the diet used by similar class of people in Madras. Gastric ulcers were observed in 11 per cent of the animals fed on a diet corresponding to that of the Madras labourer, consisting of rice, chillies, tamarind kunjee and a little fish, while 27.7 per cent of the animals fed on the Travancore type of diet consisting of tapioca root, rice, red pepper, rice water and a little fish showed ulceration and 11 per cent inflammation of the gastro-duodenal tract.

On the basis of these observations, the dietary details and their possible significance may be outlined. Taking the gastric analysis as a criterion of the response of the gastro-intestinal tract to the dietary habits of the individual the following graphs may be analysed.

The graphs represent the normal limits of the gastric acidity in 80 per cent of the cases

examined. Graph II is that worked out by me from 100 healthy adults of South India (Rao, 1937); graph III (Ghosh, 1937) from 25 healthy adults of Bengal closely resembles that by Napier and Das Gupta (1935). Graph IV, that given as standard by Bennett and Ryle, is shown for comparison. A comparison of the graphs indicates that in the first case the initial and the subsequent rise in acidity is very high and the emptying time far less. Thus it is seen that the South Indian is of hypermotile and hypersecretory type and the Bengali more akin to the normal type as described by Bennett and Ryle.

Even the pathological conditions of the stomach at the two places seem to vary to a large extent. Of 537 cases of peptic ulcer in Vizagapatam during the first quinquennial period of this decade, only 12 cases, or 2.2 per cent, perforated into the peritoneum, whereas of 303 cases for the corresponding period at Calcutta 68, or 22.4 per cent, perforated into the peritoneum. Thus, it is seen that the perforating acute type of ulcer is nearly ten times more common in Calcutta and the chronic callous ulcer correspondingly more common in Vizagapatam. This is represented in the following graph.

Thus it is seen that both the physiological and pathological reactions of the stomach, as representative of the gastro-intestinal tract, are

markedly different in the two places. Now that the two are definitely different types, the dietary details of both may be gone into.

GRAPH V

Showing the incidence of perforation among cases of peptic ulcer.

and milk products are a delicacy. The analysis of the diet is given in the following table. Comparative values of Bengal and South India are also given of the people of the same economic status.

TABLE

Showing composition of Indian diets, in grammes

	South India [Aykroyd and Krishnan (1937)]	Northern Circars [Jogiraju (1935)]	Bengal [Wilson and Mittra (1938)]
Protein ..	62.7	79	78.4
Protein, animal	9	10.8
Fat ..	26.9	15	19.7
Carbohydrate ..	488.9	619	562
Calcium ..	0.31	..	0.47
Phosphorus ..	1.51	..	2.19
Iron ..	0.033	..	0.027
Total calories ..	2,399	2,858	2,743

N.B.—The figures in these columns do not exclude the 10 per cent of wastage.

From the above figures and details one is justified in summarizing the findings as follows :—

The peculiarity of the South Indian diet—

1. The adequacy of the calorific requirements, mainly from carbohydrates.

2. The great excess of carbohydrates.

3. Lack of animal proteins.

4. Deficiency of vitamins in general.

The Bengali diet, according to Wilson and Mitra (1938), is deficient in animal protein and fat, with excess of carbohydrate and adequacy of vitamins, thus differing from the South Indian diet in the adequacy of vitamins only.

The former or the South Indian diet being the diet of the more frequent victim of ulcer may be considered in greater detail. It is the common opinion that the South Indian diet is 'rough' and more highly spiced, which may lead to ulcer formation. But it is quite probable that the human diet in no way approaches the gross 'rough' experimental diet with which ulcers have been produced (Fauley and Ivy, 1930). And the highly spiced diet can be responsible only in one way, i.e., setting up local inflammation. On a routine examination of the stomachs of all autopsies carried out during two consecutive years in Vizagapatam, it was found that gastritis was very rare. Moreover, on a routine examination of the gastric analysis of 150 healthy unselected individuals of the area, on the same diet, in not one case was there evidence of excess of gastric mucus, indicative of gastritis. Hence the improbability of the spiced diet being the aetiological factor.

The inadequacy of the animal protein may next be considered. Peptic ulcer develops only on well-marked reduction in total (Hoelzel and daCosta, 1932a and 1937, and Weech and Paige, 1937) protein intake, as in starvation and not necessarily in that of animal protein. Hence the inadequacy of animal protein, without reduction of total protein, may not be significant. But yet, probably amongst the low-paid labour classes in South India, whose protein consumption is calculated to be as low as 35.9 grammes (Aykroyd and Krishnan, 1937), this factor is to a certain extent responsible, as it has been experimentally proved that in cases of protein restriction, peptic ulcers are more easily developed with excess of carbohydrate intake (Hoelzel and daCosta, 1932). Hence probably the high daily carbohydrate intake of 650 grammes, coupled with a markedly low protein consumption of 35.9 grammes in these low-paid labour classes may be a factor in the production of peptic ulcer. This point requires further clarification.

Of the various amino-acids in animal proteins, Aron claims to have shown recently that histidine deficiency gives rise to peptic ulcers, but his theory is not generally accepted (Rao, 1938a).

Excess of carbohydrate is said to prevent the absorption of the other principles of the diet, but quantitatively it is known that a pure carbohydrate test meal *per se* produces no significant difference in test meal findings from a pure protein or a pure fat test meal (Barrow, 1932). Hence, probably, excess of carbohydrate does not influence the gastric pathology by itself, but

in conjunction with low protein as shown previously.

Regarding the fat-soluble vitamins, the table indicates their marked deficiency.

Though hypomotility of the gastro-intestinal tract is reported in vitamin-D deficiency (Ané *et al.*, 1931), this deficiency may be ruled out in a sunny tropical country like ours, but this does not apply to vitamin A. Deficiency of the anti-infective vitamin predisposes to infection of the gastro-intestinal tract as well as of the other mucous membranes, and if Rosenow's streptococcal theory be accepted there is a fruitful source of ulcer formation, but against this is the fact that hypovitaminosis A on experimental evidence (Woolback and Howe, 1925) gives rise to hyposecretion of the mucous membranes with little involvement of the glandular epithelium or glandular secretion (Verder and Petran, 1937). In typical chronic peptic ulcer, it is the reverse that is commonly seen, namely, a hyperplasia of the active secretory mucous membrane, around the ulcer area. Even in the so-called pre-ulcerous condition—a definite pathological entity—one finds a hyperplasia and hypersecretion. Hence I am of opinion that hypovitaminosis A has no place in the ætiology, though some workers claim that it has (Manville, 1933, and Santi, 1931).

Next passing on to vitamin C, it is proved (Ranganathan and Sankaran, 1937, and Rao, 1938) that avitaminosis C exists fairly commonly in South India, and hypovitaminosis C is known (McCarrison, 1921, and Smith and McConkey 1933) to produce peptic ulcers. It may be argued that if tissues are starved of vitamin C the healing of an acute ulcer may be delayed, the delay in healing being attributed to the damaged endothelium of the vessels, said to be one of the pathological changes in scurvy. It has, however, been shown recently by Bentsáth *et al.* (1936) that scurvy is a deficiency disease caused by the combined lack of vitamin C and vitamin P. According to their conception, it is a group of substances, flavones, tentatively termed vitamin P, that are responsible for the favourable effect on the resistance and permeability of the capillary wall in the pathological conditions. The rarity of genuine reports of scurvy in South India makes one believe that though deficiency of vitamin C is present there is an adequate amount of vitamin P preventing capillary fragility. Hence, probably, avitaminosis C does not play a part in the ætiology of chronic gastro-duodenal ulcers.

Next we come to vitamin B. Webster and Armour (1934) have shown experimentally that it is vitamin B and *not* the other vitamins A, D or C that is responsible for the proper functioning of the gastric glands. Rowlands and Browning (1928) have shown that avitaminosis B leads to atony and visceroptosis. Cowgill *et al.* (1926) have shown on experimental evidence that anorexia and disturbances in action of gastric musculature are symptoms of vitamin-B

deficiency. Rose *et al.* (1930) have shown that these symptoms are not due to any indirect action of the altered carbohydrate metabolism in vitamin-B deficiency, but due to direct deficiency of the vitamin itself. The fact that, in the large majority of hospital cases, the pre-ulcerous condition starts with anorexia and dyspepsia should be noted. Moreover, the gastric atony is commonly seen on the x-ray screen in these patients, and it has been experimentally shown that *prolonged* avitaminosis B leads to gastric atony (Smith, 1927). Moreover, it has been shown by blood pyruvic acid estimations (Rao, 1938c) that a mild hypovitaminosis B exists in these patients from South India.

Prolonged deficiency of vitamin B has been shown experimentally to give rise to gastric and duodenal ulcers resembling those of peptic ulcer in man (Howes and Vivier, 1936, Sure and Thatcher, 1933, 1934, and Sure and Harrelson, 1937).

I will conclude by considering the possible ways by which deficiency of this vitamin may be responsible for the production of ulcers.

1. It has been observed that in vitamin-B deficiency there is a definite increase in hæmoglobin and total blood solids; an increase in blood concentration resulting from either restricted water intake or vitamin deficiency *diminishes* the motor activity of the stomach (Rose *et al.*, 1930a).

2. Not only diminished but also irregular gastric motility is observed in vitamin-B₁ deficiency. This may lead to stasis and putrefactive changes, which evoke abnormal sensory stimuli resulting in pylorospasm (Magee *et al.*, 1929).

3. Degenerative changes were found in the adrenal, in experimental B₁ deficiency, which lead to increased histamine-like bodies in circulation, and a greater susceptibility to ulcer formation.

4. McCarrison observed that the histopathological changes in the intestinal mucosa in general, and gastro-duodenal mucosa in particular, in monkeys fed on an autoclaved rice dietary, chiefly deficient in vitamin B and to a certain extent vitamin A, consisted of—

- (i) congestion and hæmorrhage,
- (ii) atrophy of the myenteron,
- (iii) degenerative changes in the myenteric plexus of Auerbach,
- (iv) atrophic, necrotic and inflammatory changes in the mucous membrane, and
- (v) partial disappearance of the lymphoid elements of the mucous membrane.

5. The acute ulcer that is due to any of the many causes may be prevented from healing by the development of submucous œdema, and the chronicity maintained. On all the grounds above stated, one finds that it is more the submucous and the muscular layers that are involved in vitamin-B deficiency and hence the greater chance for the chronicity to be maintained once the acute ulcer or erosion is formed.

Probably, one is justified in stating on experimental evidence that the chronicity of the ulcers seems to be related to the duration rather than the degree of deficiency (Dalldorf and Kellog, 1932).

Thus, in conclusion, I think one is justified in stating that diet, specially vitamin-B deficiency in the diet, plays a definite rôle in the causation of this disease in India, if not in its onset (Rehfuss, 1927), certainly in its chronicity.

Discussion

Dr. Napier opened the discussion by questioning the validity of the observation regarding rapid emptying of the stomach in cases from South India : he noted that the acid curve terminated at 1½ hours, by which time the stomach would not usually be empty. He was also of the opinion that if statistics from medical wards were taken, a greater incidence would be shown in Calcutta, as was his experience in the Tropical Diseases Hospital.

Dr. Rao replied, 'the type of meal used in gastric analysis being the carbohydrate meal, the absence of the starch reaction to iodine gives definite evidence of the emptying of the stomach, unlike the alcohol meal.

The statistics of the medical wards were not particularly included, as the medical statistics are not so definite as the surgical statistics, because many allied conditions may be diagnosed as peptic ulcer, but the diagnosis on the operation table constitutes the correct diagnostic evidence in the surgical statistics'.

Dr. Sankaran questioned the rationale of including the disease of peptic ulcer as pre-eminently nutritional, or even as under the scope of a public health worker.

Dr. Krishnan argued that the evidence was piling up to show that diet plays a definite rôle in the disease.

Dr. G. Panja argued that if vitamin-B deficiency was responsible for ulcer formation in the stomach, it may also be responsible for the ulcer formation in the intestines as well. He further argued that if vitamin-B deficiency gave rise to ulcers, adequate vitamin-B therapy should heal up the ulcer.

Dr. Rao replied 'as peptic ulcer cannot form in the absence of hydrochloric acid, except rarely as in tuberculous ulcers, any dietetic factors that are responsible for ulcer formation in the stomach or duodenum cannot give rise to ulcers in the intestine, where the hydrochloric acid is neutralized and hence non-ulcerous conditions only can be encountered in the intestines.

In fact, the Continental and American workers are including vitamin B and vitamin C as a routine in the dietetic treatment only on presumption; but how far it is useful as a therapeutic agent cannot be vouchsafed at present'.

Dr. Ghosh argued that hypo-proteinæmia and vitamin deficiency cannot be factors on the ground that in other countries, where the ulcer

is equally as common as in India, the same deficiency does not exist.

Dr. Rao : 'It is only suggested that these factors in the diet may play an important part in the ætiology of the disease in India, just as other factors like alcoholic gastritis, nervous factors, and hyper-proteinæmia may be held responsible in other countries'.

Medical News

SUMMARY OF TUBERCULOSIS NEWS FOR THE MONTH OF JANUARY 1939

HER EXCELLENCY LADY LINLITHGOW laid the foundation-stone of a new tuberculosis hospital at Nagercoil in Travancore State on the 11th January, 1939.

Lady Marjorie Erskine opened the new Linlithgow Ward in the Government Tuberculosis Hospital, Tambaram (Madras), on the 17th December, 1938.

Lady Brabourne performed the opening ceremony of the 'Shibkumari Chetlangia Cottages' in the Judabpur Hospital, Calcutta, on the 9th January, 1939.

The first course for the training of tuberculosis health visitors under the King George Thanksgiving Fund started at Delhi on the 16th January. Ten matriculate girls from different Provinces and States in India have been chosen for a six months' course at the Silver Jubilee Tuberculosis Hospital and the Lady Reading Health School, Delhi.

NATIONAL INSTITUTE OF SCIENCES OF INDIA

BREVET-COLONEL R. N. CHOPRA, C.I.E., K.H.P., M.D., S.D. (Cantab.), F.R.C.P. (Lond.), I.M.S., has been elected President for the year 1939.

UNRELIABLE ANTI-TOXIC SERA

THAT reliance on anti-toxic sera sold in India in open market might well entail the serious risk to the life of a patient is revealed by the fact that, as in the case of the many pharmaceutical preparations recently tested, anti-toxic sera, too, purchased in the open market, have been found to be much below the indicated strength, while on occasions they are even wanting in anti-toxic action.

This shows once again how very necessary the control of drugs, especially of those whose potency has to be relied on for treatment of emergent conditions, is in the case of therapeutic and prophylactic sera, which are the only powerful weapons available for the treatment of diphtheria, tetanus and other serious bacterial infections.

In England and many other western countries, sale of no anti-toxic sera, either manufactured locally or imported, is allowed unless each batch is submitted for testing by a control laboratory established for that purpose. The tests carried out include not only the estimation of the number of 'International Units' which each serum contains, but also the sterility and innocuousness of the product.

Certain specified institutes, such as the State Serum Institute, Copenhagen, and the National Institute for Medical Research, Hampstead, maintain standard serum preparations which are identical and issue these at six-monthly intervals to testing and manufacturers' laboratories. Their use for comparison of potency of sera enables the unitage of products to be specified in an exact manner.

The potency of anti-toxic sera can be measured by biological methods, with a high degree of accuracy.

International standards for the different sera in use have been established by the Biological Standardization Committee of the League of Nations, and these enable the exact strength of any serum to be determined. Methods have been worked out by which tests can be made against the 'International Standards' and the medical practitioner using a serum which has passed an official test and is declared to contain a specified number of anti-toxin units, can rely on the potency of the serum and also administer a correct dose.

XV ALL-INDIA MEDICAL CONFERENCE

RESOLUTIONS

THE following were amongst the resolutions passed at this conference:—

The conference requests the provincial governments to formulate National Health Insurance schemes in their respective provinces and urges them to appoint special committees to formulate schemes suitable to their needs.

In view of the fact that in future wars are not going to be confined to the fighting forces alone but would affect the civil population as well, this conference requests the provincial governments to institute a survey of all the available medical resources in their respective provinces which can be requisitioned at short notice to give relief to the civil population in cases of emergency arising out of air raids and other eventualities and to give facilities to medical practitioners to obtain necessary training in this regard.

This conference is of opinion that in every province of India either the Minister in charge of the Medical Portfolio or the Parliamentary Secretary should be a member of the medical profession.

In view of the fact that facilities for medical relief and measures for the prevention of diseases existing in this country at present, particularly in rural areas, are wholly inadequate, this conference is of opinion that the same should be improved—

- (a) by subsidizing medical practitioners possessing registrable qualifications to settle down in rural areas;
- (b) by establishing dispensaries in such places; and
- (c) by better equipping the existing hospitals.

That in the opinion of this conference all teaching medical institutions should provide facilities for research, and while requesting Government to institute research fellowships for the purpose, is further of opinion that facilities for research should also be provided in these institutions to such members of the independent medical profession as may desire to avail of the same.

This conference, while appreciating the efforts which are being made in various provinces to put the teaching and the practice of the indigenous systems of medicine on a sound footing, is of opinion that no person intending to practise these systems should be allowed State-recognition unless he passes after a preliminary general education, not below the standard of matriculation examination of Indian universities, through a course of training and instruction given by competent teachers in recognized institutions—

- (a) in the fundamental sciences (*viz.*, chemistry, physics, biology, physiology, anatomy and pathology);
- (b) in Ayurvedic or Unani medicine, elementary surgery, obstetrics and preventive medicine;

and passes an examination in the subjects of the curriculum to be conducted by Statutory Boards to be created on the lines of the Bombay Medical Practitioners' Act, 1938.

In view of the rapid increase in the incidence of pulmonary tuberculosis in this country this conference, while welcoming the initiative taken by Her Excellency the Marchioness of Linlithgow in giving impetus to raise anti-tuberculosis funds, strongly urges upon the Central and Provincial Governments, local bodies and

the public to take energetic measures for the prevention and treatment of this disease—

- (i) by taking steps to improve the nourishment of the people and increase their resistance to the disease;
- (ii) by propaganda and other methods to educate the people on the causes and prevention of the disease;
- (iii) by providing funds for research on tuberculosis;
- (iv) by instituting tuberculosis clinics at the teaching hospitals as well as in all districts and other towns;
- (v) by increasing accommodation in the hospitals and sanatoria for tuberculosis patients and providing domiciliary treatment;
- (vi) by establishing preventoria for children exposed to infection, and after-care colonies for patients suffering from chronic tuberculosis and
- (vii) by collaboration of the various local committees with the local branches of the Indian Medical Association in promoting anti-tuberculosis schemes.

This conference is of opinion that in view of the unanimous decision of the Delhi conference on Medical Education in India held on 7th November, 1938, this conference requests the provincial governments—

- (i) to take early steps to establish a uniform minimum standard of medical education in their respective provinces, the standard being that of university degrees, and
- (ii) to abolish all examining bodies, other than the universities, which may be granting medical diplomas and licences.

This conference requests the Central and Provincial Governments to pass Acts—

- (a) prohibiting the publication of obscene literature and advertisements advocating the claims of the efficacy of various drugs and appliances;
- (b) controlling and regulating the public advertisements of patent and proprietary medicines;
- (c) requiring the printing on the labels of patent medicines, the names of their manufacturers, their composition, and the date and country of manufacture; and
- (d) prohibiting the publication of the description of their properties and indications for use excepting in the medical press.

This conference welcomes the appointment of the National Planning Committee by the Working Committee of the Indian National Congress and recommends that it should include schemes for the manufacture of drugs and medical appliances in India for the requirements of the country amongst the items of its deliberations.

This conference notes with concern the increasing evil of quackery in the country and the use by unqualified persons of various designations and letters simulating recognized medical degrees or diplomas and requests the Central and Provincial Governments to take necessary measures to protect the public and the profession from the consequences of this evil.

This conference urges upon Government the necessity of making it a penal offence for anyone to use the prefix 'Doctor' or 'Dr.' before his name unless he possesses a degree of doctorate from any recognized university or possesses a medical qualification from one of the medical institutions recognized by the Indian Medical Council or a Provincial Medical Council.

Whereas in the interest of public health it is highly desirable to ensure uniformity of composition in the case of biological products such as sera, vaccines of organo-metallic and other special and proprietary medicines, and whereas it is necessary to provide a check on the extravagant claims put forward on behalf of patent medicines, it is resolved that the Central and Provincial Governments be requested to start, at a very early date, a central analytical laboratory and a provincial laboratory in each province to test such preparations from time to time and to report to

Government all cases where the medicines are found to be below the standard or the advertised specifications, for taking proper action.

Speech by Dr. Bhupal Singh, B.A., M.B., Chairman, Reception Committee.

HON'BLE MRS. PANDIT, MR. PRESIDENT, LADIES AND GENTLEMEN,

I consider it a privilege to welcome you, on behalf of the Reception Committee of the 15th All-India Medical Conference, to our small town of Meerut. The place is small, no doubt, when we compare it with the large towns like Calcutta, Bombay, Karachi, Madras, etc., which have had the honour of holding the conference in past years, but I can assure you that it is second to none in the warmth of welcome which it extends.

We are thankful to you all for having taken so much trouble, at such great sacrifice of your valuable time, to come to attend the conference—particularly so to the Hon'ble Mrs. Pandit, our Minister of Health, who has very kindly accepted our invitation to come and inaugurate our conference in spite of the great strain it will mean to her in her present state of health. This is a measure of the great interest she takes in matters medical and in the Indian Medical Association under whose auspices this conference is being held. You will all be delighted to know that she has recently given recognition to the U. P. Provincial Branch of the I. M. A. as an advisory body to be consulted by the Government in all matters connected with Medical Aid and Public Health. We cannot be too thankful to the Hon'ble Mrs. Pandit for this honour. I do hope the Governments in the other Provinces will follow the example and the Indian Medical Association, which is the only body representative of all classes of Medical men in India, will soon be the one authorized advisory body to the Government in the whole of India and I have no doubt the Indian Medical Association will prove itself worthy of the trust placed in it.

Ladies and gentlemen, we are passing through very important times in the history of the medical profession in India when, on account of the establishment of popular Governments in the Provinces and consequent change of the angle of their vision, changes of a very far-reaching nature are imminent regarding various medical problems such as:—

(a) *Medical education.*—We all know that the Hon'ble Dr. Rajan, the Minister of Health, Madras, has been the first to initiate reform in the system of medical education. He has, with a bold stroke of the pen, abolished medical school education in the Madras Presidency and has introduced one uniform minimum standard of medical education—the M.B., B.S. degree of the Madras University—converting a few of the medical schools into colleges preparing for it. This has removed the pernicious class system in the medical profession and has laid the foundation of perfect harmony which is bound to result in more efficient service. Let us hope this necessary reform will soon be introduced in the other Provinces. There is a universal demand for it by the profession, particularly by our licentiate brethren. In the United Provinces, the Hon'ble Mrs. Pandit has already appointed a committee to consider the question, which will be meeting soon. I have no doubt that this committee will come to the only conclusion that this reform is long overdue. Let us hope we will soon have in the U. P. another fully-equipped college at Agra preparing for the M.B., B.S. degree.

Facilities for post-graduate teaching and medical research are very meagre indeed and it is high time that adequate provision was made in connection with the teaching institutions.

(b) Another problem compelling consideration is that of *provision for suitable medical aid and health conditions for the rural areas*. It is admitted on all hands that the rural areas have been badly neglected up till now as far as medical aid goes and the rural

population is at the sweet mercy of diseases which are certainly curable if attended to in early stages. It is quite natural that the popular governments in the provinces are seriously turning their attention to this problem. The Indian Medical Association would be quite prepared to put its services as regards expert advice and men at the disposal of the provincial governments in tackling this very important problem. In this connection, I may inform you that the U. P. Provincial Branch of the I. M. A. has already submitted a memorandum to the Hon'ble Minister of Health, which is being considered by the U. P. Government.

(c) Yet another problem which we cannot ignore is that of the so-called indigenous systems of medicine—the *Ayurvedic* and the *Unani*. These systems are working side by side with the modern scientific system for the relief of human suffering. It will be absurd to belittle the services rendered by these ancient systems specially in the rural areas, where, perhaps, the only medical aid available has been through these systems. But it has to be admitted that these systems, for want of state patronage, have not only not progressed beyond a certain stage but have actually deteriorated and have not been able to keep abreast of the scientific discoveries made in the world around us. I am quite convinced that if they have the necessary support and encouragement these systems would have progressed on the same lines as the modern scientific system and then there would have been no difference of kind between the so-called indigenous systems and the modern system. There is a universal desire to modernize these systems and naturally much is being taken from the modern scientific system for the purpose—for instance the basic sciences like anatomy, physiology, etc. I would strongly urge the necessity of maintaining proper standards as there is a tendency to give a mere smattering of knowledge of these subjects. A Bill has recently been published by the U. P. Government—called the U. P. Indian Medicine Bill—which provides for a development of the Indian system of medicine and to regulate the practice thereof. This is a move in the right direction and will, I hope, help to set up proper standards by controlling educational institutions of these systems of medicine.

(d) Another point, which I would like to invite your attention to, is the report in the Press that the U. P. Government are thinking of entertaining German Medical Experts. This has, quite naturally, caused uneasiness in the minds of medical men in India. The only fair principle which should be followed in making such appointments should be to give preference to Indian, or, if no qualified Indians are available, to German doctors of the Jewish race in their cruel persecution but at the same time we must be fair to those Indians who are highly qualified—many of whom have had higher qualifications in foreign countries at huge expense, in various branches of medical science. I do hope the report in the Press is misleading and that the U. P. Government have no such intention.

Ladies and gentlemen, there are so many other problems confronting the medical profession, such as unemployment among medical men, control of drug manufacture and the I. M. S. and the autonomous Provinces, etc., which have to be considered by the conference, but I think I should not take more of your time as I am sure you must be anxious to hear our President. But before I conclude I would like to draw your attention to one more point. In conferences of this sort, much stress is, as a rule, laid on the rights and privileges of the profession. Let us make a new departure in Meerut this year and devote, in our deliberations, an equally serious attention to the duties and responsibilities of the profession as an important unit of the body politic. Let us take our cue from the British Medical Association and organize ourselves into a really living Indian Medical Association wholly devoted to the service of humanity at large and our unfortunate country in particular.

NEW HOSPITAL IN BOMBAY

'The Singhanee Hindu Hospital will be a very valuable addition to the many medical institutions provided by the philanthropy of Bombay citizens, of which we are justly proud', declared the Hon'ble Mr. B. G. Kher, Premier of Bombay, in opening the city's newest hospital at Grant Road, Bombay, on Tuesday evening.

The hospital and its annexures form a pleasant cluster of low buildings in a spacious compound. Though placed in a busy quarter in the heart of the city, an atmosphere of peace and quiet prevails within.

Dr. R. Row, Honorary Secretary to the Advisory Board, outlining the history of the hospital, said the late Mr. Pooranmull Gooljee Singhanee, who died in December 1928, after providing for some specific payments and a donation of Rs. 8,00,000 to Bombay University, left the entire residue of his movable and immovable properties for founding, maintaining and conducting a hospital for Hindus in Bombay. The bulk of the estate consisted of immovable properties which had been disposed of gradually; even now there remained a few awaiting sale. By judicious sales, a sum amounting to Rs. 25,00,000 was made to be available for the hospital, and the trustees felt that a beginning might be made to fulfil the wishes of the testator.

Dr. Row was requested by the late Mr. F. E. Dinshaw, one of the original executors and trustees, early in 1931 to study the problem and work out a scheme. It was realized that with the sum available it would not be possible to launch an ambitious scheme of a general hospital, but a modest start might be made embracing only one or two units, such as medicine and requisite surgery with an adequate out-patient department.

SPECIAL FEATURE

After visits to institutions in Calcutta and Europe, Dr. Row said that a scheme based on the model of the Hospital of the London School of Tropical Medicine and the Carmichael Hospital of the Tropical School in Calcutta was recommended. The special feature of these hospitals was that excellent work was turned out not only by way of medical relief, but also by way of additions and advances in knowledge of the many obscure conditions and treatment of disease, a result which on closer examination was found attributable to an intimate co-ordination obtaining in the organization of the institutions between the clinical observations and pathological investigations. The scheme submitted had, therefore, for its aim a more intimate association between these two functions than was usually to be found in large general hospitals or teaching institutions.

The scheme appealed strongly to the trustees, specially as they felt that it would, whilst carrying out the donor's wishes, form the nucleus of a future institution for advanced post-graduate studies in Indian tropical diseases, studies for which Indians had to travel to London or Liverpool. Efforts then made to secure accommodation from Government on suitable terms ended in failure, and owing to the death of Mr. F. E. Dinshaw in 1936, nothing could be done till March that year. The present site of the hospital was later acquired and possession obtained in March 1937. An Advisory Board representative of all sections of the Hindu community, of which Sir Purshotamdas Thakurdas is Chairman, was formed between 1936 and 1937. Building work was started in May 1937, and completed in October last.

The hospital, Dr. Row stated, consists of a fully equipped in-patients and out-patients department, a surgical department with an operation theatre and accessories, an X-ray department with up-to-date plant, a fairly complete laboratory for pathological investigation in conjunction with the clinical unit, an up-to-date mortuary, quarters, and a few cubicles for those who might not like to remain in the general wards and were prepared to pay for residence. The hospital has accommodation and equipment for 75 beds,

but for the present, he added, it was proposed to start with and maintain 30 to 35 beds.

Sir Purshotamdas Thakurdas said that the late Mr. Pooranmull Singhanee had been a prominent figure in the commercial life of Bombay coming from a family that was pre-eminently a commercial family. Hindus, and particularly Hindus with religious frame of mind, often left fortunes for building temples or feeding Brahmins, but Mr. Pooranmull left all his money to the trustees and no particular intention in which way it was to be spent.

The late Mr. F. E. Dinshaw, Sir Purshotamdas said, resolved upon spending some portion of the funds on technical education and a sum of Rs. 8,00,000 was earmarked for this purpose. A sum of about Rs. 20,00,000 was earmarked for the hospital, the whole conception and lines on which it was to be run having been mapped out by Dr. Row. A sum of money was set aside for the widow of the late Mr. Pooranmull, but when the whole estate was cleared, Sir Purshotamdas said, charity will benefit from it to the extent of about Rs. 35,00,000.

HIGHER TRAINING

The Prime Minister said it was a great pleasure to him to declare open the magnificent institution built and endowed by the munificence of the late Mr. P. G. Singhanee.

He congratulated the trustees of Mr. Singhanee's will, particularly Dr. Row, on having worked out a scheme which provided not merely medical relief, but also ample facilities for research in tropical and other diseases. The hospital would stand not only as a monument to Mr. Singhanee, but also to the far-seeing vision of those who conceived the idea of catering for a vitally important need of the growing generation of the medical profession. He hoped it would afford great facilities for young Indian doctors, who have to travel to England and other foreign countries to obtain the necessary higher training.

Calcutta, the Premier stated, owed its School of Tropical Medicine to the efforts of Sir Leonard Rogers; Bombay can now proudly associate Dr. Row's name with this fine institution.

It was his sincere hope that, in time to come, the benefit of the research work done at the institution would slowly permeate to the rural centres, where the solutions of the problems connected with health were complicated by the evils of ignorance, poverty and a low standard of life. Several diseases had recently been the subject of investigation in India, but there still remained a vast field to be explored. Treatment and prevention as applied to medicine were inseparable and the rural doctor, whether he is the subsidized or stipendiary practitioner conducting a rural dispensary, would play an important part in educating the public. As Government progress in their various schemes of rural reconstruction and medical relief, whether by providing subsidy or by encouraging indigenous systems of medicine, there would be ample room for the use of the knowledge acquired in the Singhanee hospital for relieving the suffering of humanity, being made available to all the people of the Province.—*Times of India*, 11th January, 1939.

INTERNATIONAL LIFE INSURANCE MEDICAL CONGRESS

THE next International Life Insurance Medical Congress will be held in Paris from 18th to 21st May, 1939, with Dr. P. Hornig, Berlin, Professor Sir Walter Langdon-Brown, London, as honorary presidents, and Professor M. Loeper, Paris, as chairman.

The following reports will be submitted and discussed:—

1. Consumption and life insurance.
2. Hyperthyroidism in life insurance.
3. The influence of obesity in life insurance.
4. The importance of tobaccoism in life insurance and in preventive medicine.

5. Albuminuria in life insurance.

6. The value of statistics in life insurance.

Those who wish to attend this Congress should inform Dr. P. A. Carrie, 8, Rue de Belloy, Paris (XVII).

The contribution for the members of the Congress is fixed at Frs. 200.

The contribution for persons accompanying the members of the Congress (one person for each member) is fixed at Frs. 100.

These contributions will give the right to the banquet, the evening parties and to the excursions for which the programme will be sent at a later date, and for the member of the Congress, to an account of the Congress (reports, discussions, communications).

THIRD ALL-INDIA OBSTETRIC AND GYNÆCOLOGICAL CONGRESS

THE Third All-India Obstetrical and Gynaecological Congress will be held in Calcutta during December 1939. The exact date will be notified later.

The chief subjects selected for discussion are:—

- (1) Functional uterine hæmorrhage.
- (2) Anæmia of pregnancy.
- (3) Maternity and child welfare.

Further information can be obtained from the Secretary, Bengal Obstetric and Gynaecological Society, c/o Calcutta Medical Club, 91b, Chittaranjan Avenue, Calcutta.

CENTENARY OF THE MEDICAL PRESS AND CIRCULAR

THE *Medical Press and Circular* was founded in Dublin by Dr. Arthur Jacob in January 1839 under the title of the *Dublin Medical Press*. At the time of its foundation the profession was entirely unorganized and Dr. Jacob was one of the first men to see the need for organization.

To mark its Centenary Dr. Robert J. Rowlette, who was for many years Irish editor, has written a most interesting history of the journal and its development and has woven into his account the medical history of the times.

Up to 1866 the *Medical Press* was published in Dublin but in that year it absorbed the *Medical Circular*, which was a London periodical founded in 1852 by Dr. James Yeaesley, the aural surgeon who was closely associated with the foundation of the Metropolitan Ear, Nose and Throat Hospital, and Dr. George Ross who edited the paper throughout the fourteen years of its existence. The *Medical Circular* had an eventful and successful career and in its early day carried on a more or less continuous warfare with Wakley of the *Lancet*. It also published a long series of illustrated biographies, some very adulatory and others much the reverse.

Arthur Jacob was a prominent man in Dublin, both in his speciality, that of ophthalmic surgeon, in which he carried out much research; as a teacher in the Royal College of Surgeons in Ireland, where he held the Chair of Anatomy and Physiology for 41 years; and in the medico-political sphere. His name and work were associated with rodent ulcer of the eye which for a long time was called 'Jacob's Ulcer' and also with the discovery of 'the layer of rods and cones in the retina' which was for many years described as 'Jacob's Membrane'.

He was a member of the Council and twice President of the Royal College of Surgeons in Ireland and on his retirement was presented by the College with a 'piece of plate of a value of not less than one hundred guineas' and his portrait, which was painted by Catterson Smith, R.H.A., and now hangs in the Great Hall of the College.

During its Dublin days and especially during the editorship of Dr. Archibald Jacob who succeeded his father, the journal took a very close interest in the betterment of the position of the medical profession

in Government employ under the Poor Law system 'Dispensary doctors' as they were called, and also in the development of the organization of the profession which was perhaps the most outstanding feature of the times. The 'General Medical Council' and State registration did not come about until 1858 and in the various proposals to Parliament which led up to the Act of 1858 the *Medical Press* played a leading part.

Both the Jacobs were very ardent reformers and took an active interest in every movement which aimed at the betterment of the profession, and both in its earlier and later years the journal maintained a constant warfare against quackery and unprofessional conduct, particularly of those in high places. As might be expected this brought it at times into difficulties but only once was it taken into the courts and on that occasion its costs were defrayed by public subscription.

In the nineties in common with other papers it pressed for reforms in the Army Medical Service, which removed many of the injustices and grievances under which officers formerly laboured.

Though medical politics played a large part in the editorial policy of the *Medical Press and Circular* throughout its career, it was far from being its major interest. In its early days it was very catholic in its contents and Dr. Rowlette records that it reported in its early volumes the proceedings (among others) of the Royal Society of London, the Zoological Society of London, the Royal Irish Academy and the Academy of Sciences of Berlin. As time went on the scope was narrowed down to medicine and a high standard of original communications has always been maintained.

In recent years especially the *Medical Press and Circular* has pursued an editorial policy of providing in concise and authoritative articles the latest accepted methods of diagnosis and treatment, and has continued to occupy a useful and influential place among current medical periodical literature.

Dr. Rowlette's 'History' is very artistically produced. It is illustrated with ten plates, which include portraits of the early editors. It is a tribute worthy of the great occasion, the centenary of what is to-day one of the practitioner's most useful journals.

LIVERPOOL SCHOOL OF TROPICAL MEDICINE. MARY KINGSLEY MEDAL

At a reception held on the occasion of the presentation of the Mary Kingsley Medal at the Liverpool School of Tropical Medicine on 23rd November, 1938, the Chairman welcomed the guests.

This is the second time, he said, that I have been privileged, on behalf of the council, to present these medals which are the highest distinction which the school can bestow.

On the last occasion in 1934, I had the honour of reading a message from H. R. H. the Duke of York, who was then our President. After ascending the throne, our former President honoured the school by graciously accepting the office of Patron. At the Annual Meeting this afternoon, a telegram of loyal wishes and dutiful appreciation was sent to the King and the following gracious reply has been received:

I sincerely thank the council and friends of the Liverpool School of Tropical Medicine for their kind and loyal message. As Patron, I am glad to know of the presentations of medals which are being made this evening and assure you of my continued interest in the work of the school'.—GEORGE R. I.

I am sure that all associated with the school are gratified to have this token of His Majesty's continuing interest in its work.

When the office of President became vacant, as I told the Annual Meeting this afternoon, there seemed to be only one person who could be first asked to fill it—Lord Derby—and he most kindly consented to do so.

The Mary Kingsley Medal was founded in 1904 to commemorate the work of Mary Kingsley, whose father was Charles Kingsley the novelist, in promoting the welfare of the natives of West Africa. Mary Kingsley

had personal associations with Liverpool, so it is most appropriate that this distinction should be linked with her name. The qualification for a recipient of the medal are services in the cause of preventing and fighting disease in the tropics. There have been many distinguished recipients in the past and the standard is well maintained by those whom we are honouring to-night. When introducing them, Professor Warrington Yorke will speak with more authority and in greater detail about their scientific qualifications than I can, but I would like to suggest that their acceptance of this honour is yet another example of the international character of all true science. Dr. M. A. Barber is at present working in Mexico and so unfortunately cannot receive the award in person. In Emeritus Professor Patton we have one who was a Professor here for ten years and a distinguished British entomologist, while Professor Brumpt comes from Paris and Professor Schulemann from the University of Bonn in Germany. Finally there is the award which I feel sure will give the greatest possible pleasure to her friends in this neighbourhood, the one to Lady Danson, whose husband was Chairman of the school and one of its founders. It has become customary, when awarding these medals, from time to time to step outside the ranks of scientific workers and honour the names of those who, although not technologists, will always remain associated with the progress of Tropical Medicine. We have the happiest memories of the late Sir Francis Danson, whose son is a member of our council, and I am sure you will agree that Lady Danson is a most fitting recipient of a Mary Kingsley Medal.

A little while ago, I happened to see a performance of a one-act play by Neil Grant in which one of the characters is a microbe. The play is called 'The Last War' and suggests that, in the final Armageddon, when the warring nations are busy cancelling each other out, after bullet, shell, bomb and gas have done their worst, the entomologist will be harnessed to a chariot of war and the parasitologist will put on the armour of Mars in order to complete the holocaust. The play depicts a group of animals discussing the situation after the last specimen of *Homo sapiens* has been wiped out. Actually in the play one soldier escapes, but that is by the way. The play gives rise to some awesome thoughts, for one certainly feels that, however much scientists in other fields may turn their attention to new means of destruction, medicine in general and tropical medicine in particular will always be devoted to the saving of life only.

It is an interesting thesis, but meanwhile the school continues on its beneficent way. I can hardly believe that Professor Warrington Yorke, even if he were willing to try, could call a halt to his long campaign against the bacillus, and persuade it to be his ally instead of his enemy, or that Professor Gordon, even with all the resources of the Insectarium, could raise a race of microbes which would obligingly take sides in a world war. Forgive this digression.

Before calling upon Professor Warrington Yorke, I would like to call your attention to two significant anniversaries. This year marks the fortieth anniversary of the founding of this school and it is just half a century ago that the late Sir Ronald Ross made the great discovery of the transmission of malaria by the mosquito. To realize what that means, we have to try to imagine what the tropics would be to-day if the discovery had never been made; what life there would be like if, although doctors might know how to treat and cure malaria, they had no idea how it arose and no knowledge of what sanitary precautions had to be taken to prevent it. It was an epoch-making discovery and this school can be proud to recall that Ross became a member of the original staff here and accompanied a succession of expeditions sent by the school to various tropical regions.

LADY DANSON

The first Mary Kingsley Medalist on this occasion is a lady distinguished in many ways and well known to us all. By this award we convey our appreciation of the part which she has taken, and is still taking

in promoting the investigation of tropical diseases, thus furthering the endeavour of her late husband.

The association of Sir Francis Danson with this institution began very early in its history. As you have heard, the school was founded in the year 1898; and already, in 1901, we discover Mr. Danson representing the Council of the University on the school committee. In 1908 he attained the office of vice-chairman, and in 1913 he succeeded the late Lord Leverhulme as Chairman of the School, a post which he continued to hold until his death in 1926.

It was during his lengthy period of office as Chairman that he saw the establishment of the school's research laboratory at Freetown in Sierra Leone, West Africa, for the construction of which a sum of £10,000 had been bequeathed by the founder of the school.

Sir Francis Danson took a deep interest in the opening of this West African laboratory, and, while he fully recognized the strain which this scheme must throw upon the limited financial resources of the school, he felt so optimistic about the prospects of research there that he urged the professional staff and committee to risk the venture, leaving for the future the question of adequate endowment of the laboratory. From the scientific point of view his optimism has been justified. The Sir Alfred Lewis Jones Laboratory in Freetown is an institution which has made valuable contributions towards the solution of many problems of tropical disease.

In the year 1920 Mr. Danson's services to this school and to other public bodies in Liverpool were rewarded by the conferment of a knighthood. How great a part he played in the life of Liverpool could only be gauged from a full recital of the number of important offices he held—a recital too long for an occasion such as this.

But Lady Danson was far from idle during all the years in which her husband presided over the destinies of the school. She was not content to be a passive spectator of its rapid development, but took the keenest interest in all its varied and sometimes disconcerting phases. On occasions, during her husband's enforced absence owing to sickness, she found herself suddenly called upon to assume, at public functions, the duties of Chairman. It was at such times that she revealed, somewhat to the surprise and greatly to the enlightenment of members of the committee and of the professional staff, not only that she had a thorough grasp of the affairs of the school, but also, incidentally, that she herself was no mean orator.

It is, therefore, no less on account of her own faith in the future of the school than in recognition of her late husband's long services to it that we have particular pleasure in awarding the Mary Kingsley Medal to Lady Danson.

MARSHALL ALBERT BARBER

Seventy years ago—to be precise, 70 years ago yesterday—Dr. Marshall Albert Barber was born at Crown Point, in India. I suppose that, like other children born in India, he was tormented by mosquitoes. If this be so, he has exacted a full revenge from these enemies of mankind, for during the past quarter of a century he has devoted himself to the study of their habits, and has added greatly to the knowledge of how best they may be destroyed.

Amongst his many contributions to this branch of science, there ranks foremost his discovery of the manner in which 'Paris green', an arsenic compound, can be used as an effective and inexpensive means of destroying the larvæ of malaria-carrying mosquitoes—a discovery which has benefited mankind in every part of the world where malaria afflicts the human race.

Dr. Barber's long and distinguished association with the International Health Division of the Rockefeller Foundation is well known, not only on account of his researches in malaria, but also for work on the hookworm. During his visit to the Orient in 1915-1917, Barber published papers on both these diseases, and showed clearly for the first time the part played by each in producing the anæmia which is so pronounced

a feature of the inhabitants living in districts where the diseases are endemic.

A man more versatile than most of his fellows, he has in his time laboured in many fields of science, for he was an Assistant in Botany at Harvard as long ago as 1892, and became Professor of Bacteriology and Pathology at Kansas at the early age of 26. It was during this period of his career that he invented the apparatus with which his name will always be associated, the 'Barber micro-manipulator'. This instrument, like so many great inventions, was simple in its original conception, but its introduction marked an important advance in medical science, for by its aid bacteriologists are now able to study the growth of individual minute organisms, and biologists to dissect individual cells, under far higher magnifications than were previously possible.

Dr. Barber has had an exceptionally long and distinguished scientific career. Thirty-five years ago he published his first important contribution to medical science, and to-day, at 70 years of age, he still continues, with that indefatigable zeal which is so characteristic of him, to add to the store of human knowledge by his studies of malaria in India and America.

We much regret that Dr. Barber, who is at present working in Mexico, is unable to be with us to-night; but we are pleased to welcome his distinguished colleague, Professor Gunn, vice-president of the Rockefeller Foundation, who has kindly consented to receive the medal for him.

EMILE BRUMPT

We honour next Professor Brumpt. Professor Emile Brumpt was born in Paris in the year 1877. He studied at the Sorbonne and in the Faculty of Medicine of Paris, and was awarded the degree of Doctor of Natural Sciences in 1901. He became a Doctor of Medicine in the year 1906, presenting a thesis on Mycetozoa. In 1907 he was appointed Associate Professor of Parasitology and Natural History in the Faculty of Medicine, and in 1919 he attained full professorial status.

It was in this year also that he was elected a member of the Academy of Medicine, and it was not long before he was being honoured by membership of numerous foreign scientific academies and societies. In the same year he undertook the heavy duties of Secretary-General of the Institute of Colonial Medicine of France, which he still carries out with energy. In the year 1926 he was appointed director of the School of Malariology of the University of Paris.

Professor Brumpt is the author of over 350 published papers, covering a wide field of scientific investigation. One of his outstanding contributions to the wider dissemination of knowledge of the subject of parasitology was his foundation of the *Annals of Human and Comparative Parasitology*, a journal which he has directed from its inception. His name is familiar to students in every country from the popularity which has been attained by his well-known textbook on parasitology, of which compendious tomes—there are two of them—the fifth edition has recently appeared.

Brumpt, the professor, the scientific and successful investigator into innumerable problems of tropical parasitology, is a name to conjure with in every centre where research in parasitology is in progress. Brumpt, the man, is certainly one of the most familiar medical figures in the world to-day. He has for many years been an indefatigable traveller, and the celerity of his meteoric excursions over the surface of the globe is something quite remarkable. No form of transit is too rapid for him. The directors of railway, shipping and airline companies must all bless the name of Brumpt—that is, of course, assuming that he is always a fare-paying passenger. If one wishes to discover Brumpt, one may look for him almost anywhere in the wide world with an equal chance of success. He may be in China or Peru, on the Amazon or the Euphrates; he may be sitting chilly on the rocky mountains or plunging in perspiring haste through the forests of equatorial Africa. Wherever he is found

he will always be the same alert, earnest investigator. He is the personification of the ardent spirit of research, filling each 'unforgiving minute with sixty seconds' worth of distance run'.

WALTER SCOTT PATTON

In honouring Professor Walter Scott Patton we are honouring a colleague who has worked for ten years with us in this school.

Patton was born in India in 1876, and, after obtaining his medical degree in Edinburgh and spending some time in postgraduate study in Germany, he joined the Indian Medical Service in 1902 and returned to the land of his birth. Here for twenty years he laboured, adding much to our knowledge of the diseases of that country. The Indian Medical Service contains the names of many who have achieved fame in science, and Patton's occupies a place of honour amongst them. The routine duties of an officer in the Indian Medical Service are manifold and arduous, yet, like his comrades Ross and Leishman, Patton always found time—the time that most men would have devoted to recreation—to pursue his investigations. The value of his work was early recognized by his appointment as a specialist to investigate the etiology of Kala-azar and Oriental sore, and later by his promotion to the Directorship of the King Institute of Preventive Medicine in Madras.

In 1921, he joined the staff of the University of Edinburgh. He was not, however, allowed to remain long in this academic sanctuary, for in 1925 the Royal Society organized the Kala-azar Commission to Northern China, and selected Patton to be its Director.

In 1927, Patton was appointed to the Dutton Memorial Chair of Entomology in this University. During the ten years which he has occupied this Chair his kindness and courtesy endeared him to all with whom he came in contact; and it was with the very deep regret of all his colleagues that it was learned in December last that he had been compelled to resign owing to ill health.

With a modesty rare in this self-seeking age, Patton has been content to work long and arduously, seeking only to help his fellow men. In this country, in India and elsewhere there are colleagues who owe much to their association with him, and scattered over the world there is an army of students whom he taught with that patient care and attention to detail which are characteristic of the man. But there is another and far greater army who, though they have never met him, know him through his books. They are formidable, imposing volumes, these Debretts of the entomological world, whose pages you examine with the comforting thought that if it is not in 'Patton' it is not worth while. Not, perhaps, books to be lightly read, but rather with the feeling that

'Here index learning turns the student pale
Yet holds the eel of science by the tail'.

We all regret that Professor Patton is unable to attend to-night to receive the medal in person. But he is represented by a colleague who has worked with him for 32 years—one who has rejoiced with him in his many successes and shared his few failures, and who has added much to the interest and scientific value of his numerous publications by those exquisite drawings which bear the well-known signature E. M. P. I refer, of course, to his wife, whose presence here to night gives us all great pleasure.

WERNER SCHULEMANN

Professor Werner Schulemann was born in Silesia in 1888, and was educated in the Universities of Freiberg and Breslau, where he studied chemistry and medicine. He gained his degree in science in 1913, and graduated in medicine the following year. After the War he joined the great German chemical firm of Bayer, and soon rose to the directorship of that firm's celebrated pharmacological laboratories at Elberfeld. There he devoted his remarkable gifts to the study of pharmacology; he synthesized new chemical compounds which are now widely used as local anaesthetics and soporifics and for a variety of other medicinal purposes. His

researches on the relationship between chemical constitution and pharmacological activity have received universal recognition.

Although Schulemann has never visited the tropics, his researches at Elberfeld have resulted in a discovery of such importance to tropical medicine that his name is known to all workers in this field.

In order that you may appreciate the full significance of Schulemann's work I must take you back to 1905, when the late Dr. Wolferstan Thomas of this school discovered that it was possible to cure animals infected experimentally with the sleeping sickness organisms by means of a practically unknown and unused proprietary substance called 'atoxyl'. This substance, which was soon shown to be a compound of arsenic and aniline, was immediately tried with striking success in cases of human sleeping sickness, which at that time was destroying hundreds of thousands of lives in Tropical Africa, and for which we had no remedy.

This empirical discovery—that it was possible to cure the fatal infection by a chemical compound manufactured in the laboratory—called forth Ehrlich's classical researches, which culminated a few years later in the production of salvarsan, or '606', as a cure for syphilis. The modern science of chemotherapy—the treatment of infectious diseases by chemical substances—was thus established on a sure foundation, and soon other compounds were prepared whereby many of the deadly diseases of the tropics can now be cured.

The problem of malaria—the greatest of all tropical diseases—still remained. Fortunately, we were far from unarmed in our warfare on this disease, because nature had provided a remarkable remedy in quinine. Nevertheless, the efforts of the chemist had failed to produce any drug which was of the slightest value in the treatment of malaria.

In 1924, Schulemann published a discovery of the greatest importance. He had succeeded in synthesizing in the laboratory a chemical compound which not only acted on the malaria parasite, but accomplished what quinine had failed to do, in that it destroyed the stage of the parasite which infects the mosquito. This outstanding achievement attracted world-wide attention and gave a great impetus to the comparatively new science of chemotherapy, the full significance of which is only now beginning to be appreciated.

Although Schulemann is the last of the distinguished scientists whom we are honouring to-night, he is certainly not the least. Beneath his formidable exterior is a genial and kindly nature which has made for him a host of friends in many countries. A man of wide interests and accomplishments, he touches life at many points. He speaks four languages fluently, and has a profound admiration for all that is beautiful: to visit the galleries of Rome under his guidance is a delight.

Two years ago Schulemann left the firm of Bayer to become Professor of Pharmacology at Bonn: he has the best wishes of all his friends in his endeavour to create at that ancient seat of learning a department worthy of the great subject which he adorns.

Anæmia and Disorders of the Blood

By L. E. H. WHITBY, C.V.O., M.D., F.R.C.P.

(From the *Practitioner*, Vol. CXLI, October 1938, p. 453)

THE erythron is a system, the activities of which are delicately balanced to meet the requirements of the rest of the body. Hence, disease in any place may give rise to changes in the circulating blood. Such changes may be acute, chronic, progressive, or perhaps so slight as only to be apparent in a series of observations. Much study has been devoted to establishing the blood findings of different diseases, but only rarely are such findings diagnostic. Furthermore, with

the striking exceptions of leukaemia and aplastic anaemia, almost all blood changes are signs of disease and not a disease *per se*. Like all other physical signs, blood changes are most easily recognized and assessed at the time when the patient first seeks advice, that is, before symptomatic treatment with haematinics or other drugs has obscured valuable haematological features. Every case of anaemia should suggest the question 'Why?' and this should be answered whenever possible, before treatment is begun.

Haematological examinations require time and a great deal of experience; frequently the preliminary investigation can be nothing more extensive than a simple blood count. If this does not provide conclusive information the more elaborate procedures of a trained haematologist are necessary. Certain tests, particularly those involving coagulation factors, require the attendance of the patient, but the majority of the important procedures in a blood examination can be performed on samples of blood measured in exact amount into tubes containing an exact amount of oxalate salts; such tubes, with instructions, are supplied by most laboratories. A modern blood examination does not stop short at an estimation of haemoglobin and red cells and a determination of colour-index: it seeks to analyse any anaemia that may be found in terms of red-cell size and haemoglobin concentration. These two factors, which are inseparately combined in the colour-index, must be separated into values known as the mean corpuscular volume (M.C.V.) and mean corpuscular haemoglobin concentration (M.C.H.C.). By so doing it will be found whether the size of the red cells is large, normal, or small, and whether the concentration of the haemoglobin in the cells is normal or low; it is not possible to have the haemoglobin concentration greater than normal because there is a physiological limit to haemoglobin saturation.

The anaemia may thereafter be classified into one of Wintrobe's four groups; these groups have been found to be of great practical value for clinical purposes. These groups are: (1) normocytic and normochromic; (2) simple microcytic; (3) hypochromic microcytic; (4) macrocytic. According to the group, it is possible to form some reasonable opinion as to the probable basic cause of the anaemia.

THE ANÆMIAS

The commonest anaemias of general practice are due to toxæmia or general debility and these anaemias are almost invariably either normocytic and normochromic or simple microcytic. The remedy is to find the cause rather than to provide a haematinic because haematinics have little effect on such anaemias. The causes occupy a wide range—a septic focus, such as a tooth or sinus, an unhealthy occupation, a non-physiological life, a chronic infection, a chronic toxæmia, or some more ominous reason such as tuberculosis, nephritis or a neoplasm. Aplastic anaemia, a rare disease, is normocytic and normochromic.

Hypochromic microcytic anaemias form most of the marked anaemias of general practice. The commonest cause is hæmorrhage and if this is from the bowel it may quite often pass unnoticed. Bleeding from the uterus, bleeding from piles and bleeding from alimentary ulcers, simple and malignant, always produces this type of anaemia. Hypochromic microcytic anaemia is found also in infantile iron-deficiency anaemias, in the idiopathic hypochromic anaemia of middle-aged women, and in Banti's syndrome.

Macrocytic anaemia comprises the pernicious type and is found in most characteristic form in true pernicious anaemia. But not all macrocytic anaemias are pernicious anaemia. A similar blood picture may be found in sprue, alimentary neoplasm, certain helminth infections, cirrhosis of the liver, and a number of intestinal disorders. Macrocytosis may also be present for a short period after an acute hæmorrhage, and in adults it is sometimes a prominent feature of hæmolytic anaemias associated with splenic enlargement which, in the present state of knowledge, are still classed as the adult or acquired form of acholuric jaundice.

With a simple blood count, a high colour-index inevitably indicates macrocytosis but the reverse is not necessarily the case; a low colour-index does not exclude macrocytosis. One other phenomenon of red cell size has to be borne in mind—the so-called 'spherocytosis' which is characteristic of acholuric jaundice. In this disease the cells appear microcytic in a stained film, but the mean corpuscular volume is relatively high because the cells are thicker than normal.

It is perhaps unfortunate that blood not more than three hours' old is required for a sedimentation test because this non-specific test is now known to be invaluable for differentiating functional from organic disease. Thus pernicious anaemia and idiopathic hypochromic anaemia, both due to stomach dysfunction, cause no increase in the sedimentation rate, whereas carcinoma of the stomach, which haematologically may closely resemble either of the two functional diseases, almost invariably increases the rate. When an anaemia is accompanied by an increased sedimentation rate it is important to look carefully for a source of sepsis (which itself may be the cause of the anaemia) or for some definite organic disease.

DETAILED INVESTIGATIONS

With the anaemia placed into its correct group, before the results can be properly assessed, the findings must be taken in conjunction with the clinical picture as well as with any other abnormalities that may be observed in the blood in the course of the routine examination. The advantage of the modern method of blood collection is that the haematologist has available a sufficiently large sample of blood with which to proceed to any investigations that are relevant. For example, supposing the blood film contains numerous polychromatic or punctate basophilic cells, it can be inferred that there is a reticulocytosis and the number of reticulocytes should be determined. Reticulocytosis is found after hæmorrhage, in acholuric jaundice, in chronic lead poisoning and chronic malaria. An estimation of bilirubinæmia, a platelet count or a fragility test (which nowadays is always performed by an exact quantitative method in order to detect minor degrees of increase in fragility), may also be indicated. The sedimentation test is performed as a routine. The leucocyte count, total and differential, is an integral part of the routine examination and may itself suggest possible causes for anaemia. The value of the leucocyte count in cases of pyrexia of unknown origin is well known; but it is perhaps not realized how essential is this simple examination with an ulcerating or hæmorrhagic lesion of a mucous membrane especially when in the mouth or pharynx. All such lesions must always raise the suspicion of agranulocytic angina or of leukaemia. Frank leukaemia is readily diagnosed from peripheral blood. The most difficult problem which confronts the haematologist is the differentiation of certain leukaemoid conditions from true leukaemia and especially when the last named presents the so-called aleukæmic blood picture. Aplastic anaemia and agranulocytic angina have also to be considered in differential diagnosis. When such illnesses are not quickly fatal it is much better that they should be investigated under hospital conditions where serial observations of the blood should provide the correct answer. Usually, however, it is necessary to examine more than the peripheral blood. Leukaemia and aplastic anaemia are primary diseases of the marrow and it is therefore essential to examine this tissue, either by sternal puncture or sternal trephine; the last named gives the more accurate picture. Quite often the state of the marrow, which is the key to the diagnosis, is not accurately reflected in the peripheral blood. Modern methods of study by supravital technique enable difficult primitive diagnostic cells to be identified. Leukaemia with its hopeless prognosis has to be most carefully distinguished from the benign infection known as glandular fever. To the experienced, glandular fever presents a characteristic blood picture, but the monocytic and lymphocytic cells which the infection produces are not infrequently mistaken

Reviews

KRANKHEITEN UND HYGIENE DER WARMEN

LANDER.—By Prof. Dr. P. Mühlens, Prof. Dr. E. Nauck, Doz. Dr. H. Vogel and Flottenarzt, Prof. Dr. H. Rugo. 1938. Published by Georg Thiemo/Vorlag/Lolpzig. Pp. 562. Illustrated with several coloured drawings and black and white illustrations. Price, RM. 43.

WITH the issue of the fourth edition, this book must now be moved up into the first rank of textbooks on tropical medicine. This is not said with any intention of disparaging the previous editions, but because they did not make any claim to be comprehensive, a claim to which this edition has the obvious right.

Professor Ruge still contributes a majority of the sections, with Professors Mühlens and Nauck as close seconds. Dr. Vogel has contributed the helminthological section, and Prof. E. Martini some of the purely entomological and the zoological sections.

The first section is logically a general one on tropical hygiene, and this is followed, not quite so logically, by a short section on the blood and blood technique.

The book is divided under a number of major headings, the first and most important of which is infectious diseases; in this is included protozoa, spirochaetes, virus diseases, Bartonella and Rickettsia. The 77 pages on malaria would have made a good monograph on malariology and a far more complete one than many that have been issued. Every aspect of the subject is dealt with comprehensively and there are numerous useful line drawings and half-tone figures showing methods of mosquito dissection and identification. Treatment has not unnaturally been given a most important place, in view of the great contribution that have come from German scientists on this subject, and recent drugs such as certuna are mentioned. Anti-mosquito methods of prophylaxis are described in some detail and again many illustrations are given.

It would be an interesting subject of psychological study as to why the malariologist cannot possibly oil a stretch of water or spray Paris green without having a photograph taken of himself doing it. On the whole, the illustrations in this book are relevant, an exception being the rather naive picture of how not to hang a mosquito net; a child of three would scarcely commit such a mistake.

The next two sections are on sleeping sickness and leishmaniasis, respectively; in each case the treatment of the subject is comprehensive, and, in fact the same can be said for each disease in this section.

The next major heading is dietetic diseases, which includes Bengal epidemic dropsy: in this section there is a reference to the work of Chopra and Mitarbeiter (*sic*), 1937, on tissue culture—this appears to be a curious misprint which is not characteristic of the book.

Then follow sections on bacterial diseases including tularemia and melioidosis (*sic*—the reviewer has accordingly revised his pronunciation of the word), helminthic and arthropodal diseases, and tropical skin diseases, in which section leprosy is included.

The last few sections are on fish and snakes, on miscellaneous subjects such as splenomegaly and tropical macrocytic anaemia, on tropical surgery, and on cosmopolitan diseases occurring in the tropics.

The worker in tropical countries will find the book an invaluable addition to his personal library and no medical institution library will be complete without it.

L. E. N.

THE BRITISH ENCYCLOPÆDIA OF MEDICAL PRACTICE INCLUDING MEDICINE, SURGERY, OBSTETRIC, GYNÆCOLOGY AND OTHER SPECIAL SUBJECTS. Under the General Editorship of Sir H. Rolleston, Bt., G.C.V.O., K.C.B., M.D., D.Sc., D.C.L., LL.D. 1938. Butterworth and Company, Limited, London. (To be completed in 12 volumes.) Sold in complete sets only. Cash price, Rs. 25 per volume. Also available on the instalment system at Rs. 10 per month. Price, Rs. 26-8 per volume. Only available from Messrs. Butterworth and Company (India), Limited, Calcutta. Volume VIII. Pp. xix, plus 664 plus 48 with 13 plates.

THE range of this volume is from leukaemia to mucous colitis. It is an important volume, as it includes comprehensive sections on diseases of two important organs, the liver and the lungs, and on that corner-stone disease of the tropics and sub-tropics—malaria.

The first chapter, on leukaemia, is contributed by that well-known haematologist, Dr. Janet Vaughan. As one would anticipate, she has made as comprehensive a survey of this important group of diseases as the space (40 pages) allowed. The chapter is enriched by a number of plates, three of which are in colour. The classification given is the generally-accepted one and the treatment of the subject is practical, concise, and orthodox. A note on the technique of sternum puncture is appropriately included here. There is much to be said for the suggestion that only 0.2 c.cm. of fluid be taken, but this does not allow sufficient for a satisfactory total nucleated-cell count of the material. In the table showing the normal findings, she places 'megablasts of Ehrlich' at 0 to 25 per cent. The authors who have given the normal range of megablasts as up to 25 per cent must be few, and we do not believe that anyone has described finding more than an occasional true Ehrlich's megablast in normal marrow. Her illustration of this cell is very poor.

Liver diseases are dealt with in eleven sections. The first is appropriately on liver function tests; this and the majority of the other sections are written by Dr. R. S. Aitken of the British Post-Graduate School, but the editor contributes the section on the blood vessels of the liver, Sir Leonard Rogers on tropical liver and Sir U. N. Brahmachari on infantile cirrhosis of the liver. Sir Leonard explains in two pages that there is no such condition as tropical liver, or alternately that it is amoebic hepatitis.

The diseases of the lung are similarly dealt with in a number of sections, abscess and gangrene, atelectasis and collapse, oedema, tuberculosis, syphilis, moniliasis, fibrosis, tumours, and post-operative complications. The chapter is not of course comprehensive and other diseases of the lungs, such as broncho-pneumonia, empyema, and pneumoconiosis have been, or will be, dealt with in other volumes. The most important is the section on tuberculosis by Dr. L. S. T. Burrell of the Royal Free and Brompton hospitals.

The chapter on lymphopathia venereum (lymphogranuloma inguinale) is an authoritative contribution by Dr. Hugh S. Stannus who has done much to disentangle the muddle over the different clinical syndromes brought about by the specific virus of this disease.

Sir Rickard Christophers who has done so much to forward the study of malaria in India has given a very valuable account of the disease from the parasitologist's point of view. It includes some good coloured plates and a useful summary of the present position regarding the treatment of malaria. The pathological section is, however, particularly disappointing, for example, the observation that the van den Bergh 'direct delayed' reaction is positive in malaria 'with the indirect reaction increased' as an unqualified statement is very misleading. The information on the blood picture is meagre and amounts to little more than the rough impressions of a parasitologist who was compelled whilst studying the morphological minutiae of the malarial parasite to include in the microscopic field certain

blood cells. One looks in vain for a histological picture of the spleen in either acute or chronic malaria.

A good account of that rare disease melioidosis is given by the late Dr. William Fletcher. Other important chapters are on meningitis by Dr. Letheby Tidy, on menorrhagia and metrorrhagia by Mr. Eardley Holland, and on mucous colic by Sir Arthur Hurst.

There is an excellent essay on metabolism by Dr. R. A. McCance which is followed by one on basal metabolism, its significance and the methods for measuring it, by Dr. Douglas Robertson.

Altogether the contributions in this volume are of a very high standard.

THE EXTRA PHARMACOPŒIA—MARTINDALE.

Twenty-First Edition in Two Volumes. Volume II. 1938. Published by direction of the Council of the Pharmaceutical Society of Great Britain. The Pharmaceutical Press, London (23, Bloomsbury Square, W.C.1.). Pp. xxxvi plus 1148. Price, 22s. 6d. Postage, 6d. extra

The story of the *Extra Pharmacopœia* is one of a 'rakes progress' and just shows what the writing of books may lead to. The first edition, published in 1883, was an innocent little volume of 313 pages; the 21st edition consists of two volumes of 1182 and 1118 pages, respectively.

With the publication of volume II, the new proprietors of this work have issued the first edition for which they were completely responsible. The Council of the Pharmaceutical Society of Great Britain took over the publication of this invaluable work after the death in 1933 of Dr. Martindale, whose father had been responsible for the first edition, and published volume II of the 20th edition, volume I having appeared in 1932.

The name, Martindale, still appears on the title page and cover and we hope it always will.

There is little change on the scope of this work, but knowledge has increased, so inevitably must it grow. The information, which is nearly all essential for the proper practice of both pharmacy and medicine, is reasonably up to date, that is to say, up to the end of 1937.

The sections on nutrition and vitamins contain concise information that should be particularly useful to the practitioner, also the sections on new ethical proprietary medicines and tests and microscopic methods for blood, urine, etc. The same might also be said of the 136 pages devoted to bacteriological and clinical notes. Again, the information given is usually up to date, but it is necessarily rather fragmentary. It is a section that will perhaps appeal more to pharmacists, for the average practitioner should have some more complete recent book of reference. Nevertheless, many will appreciate this additional source.

We cannot enumerate all the section headings in this short review, but they include a table of infectious diseases, chemotherapy, x-ray diagnosis, electrotherapy and diathermy, food preservatives, and milk and milk products.

This 'bible' of the pharmacist and analyst will prove an invaluable addition to any medical man's library.

A SYNOPSIS OF MEDICINE.—By Henry Letheby Tidy, M.A., M.D., B.Ch. (Oxon.), F.R.C.P. (Lond.). Seventh Edition. 1939. John Wright and Sons, Limited, Bristol. Pp. xix plus 1187. Price, 21s.

THERE are synopses and synopses—pure 'crum' stuff for examination purposes only, and comprehensive summaries for the practitioner as well as the student. This book certainly belongs to the latter class. Take the first subject, for example; 30 pages are devoted to typhoid. In these pages nothing seems to be redundant and little is missing.

In the present edition a large number of sections have been rewritten and nearly all others have been brought up to date. The tropical-disease sections are on the whole good, but perhaps not quite as up to date as the rest. There is, for example, no mention

of nicotinic acid in the treatment of pellagra, carbarsone in amoebiasis, or tetrachlorethylene in ankylostomiasis.

Dr. Letheby Tidy is responsible for many very valuable contributions to medical literature and this book takes a high place amongst them. It is certainly one of the best books of its kind in the English language (the last edition incidentally was translated into German) and the reviewer can strongly recommend it to both the student and the practising physician.

WHITLA'S DICTIONARY OF TREATMENT INCLUDING MEDICAL AND SURGICAL THERAPEUTICS.—By R. S. Allison, M.D., M.R.C.P. (Lond.), and C. A. Calvert, M.B., B.Ch., F.R.C.S.I. Eighth Edition. 1938. Baillière, Tindall and Cox, London. Pp. vii plus 1285. Price, 30s.

OWING to the death in 1933 of the distinguished author of this well-known work the production of the eighth edition has been taken over by two other Belfast practitioners. Recent advances have necessitated many alterations and the re-writing of the major portion of the contents. In this task the authors have not been content with doing the whole work themselves but have added to the number of special contributors and ten other names appear. All of them are Belfast men and in their hands the book has suffered no deterioration compared with the earlier editions, and it stands as a tribute to the high quality of medicine in Belfast city.

The sections dealing with tropical medicine have been well done by a worker who has had long practical experience of tropical medicine in Africa and the result is that it is free from the many errors so common in books on general medicine in which tropical diseases are included, and the information is also right up to date. Accordingly this valuable volume for ready reference can be recommended to tropical practitioners as well as to their colleagues of temperate climes.

CHRONIC DISEASES OF THE ABDOMEN: A DIAGNOSTIC SYSTEM.—By C. J. Marshall, M.S., M.D. (Lond.), F.R.C.S. (Eng.). 1938. Chapman and Hall Limited (11, Henrietta Street, W.C.2), London. Pp. xviii plus 247. Illustrated. Price, 25s.

THE 'chronic abdomen' is to the house physician what the 'acute abdomen' is to the house surgeon, his most difficult problem. He will certainly welcome this book, in which the subject is treated in a much less orthodox manner than in the usual run of books, and is approached from a definitely practical angle.

The writer, like most good teachers, has his little foibles, his likes and particularly his dislikes; he dislikes the expression 'chronic appendix'. It is a slovenly expression but it doesn't seem worth getting excited about.

The author might carry his puristic tendencies into the physiological field and not refer to the van den Bergh test as one for estimating *urobilin* in the blood.

The so-called radiological signs of appendicitis are fixity of the tip, kinking incapable of being straightened out, pain on pressure (it hardly needs a radiological examination to elicit this!) and bead-like filling defects due to the presence of transradiant concretions (these, incidentally, may be radio-opaque). But certainly the presence of these signs does not prove the appendix inflamed, nor does their absence disprove inflammation in it.

The 'chronic appendix' [we will use the expression if we want to] will test the complete integrity of the most high-minded surgeon to its limit, and beyond. This fact the writer obviously appreciates when he says 'once such a patient entertains the idea that there may be something wrong with the appendix, she (usually) is rarely satisfied . . . until someone removes the appendix and then it is only just in time! And it is quite true that although the surgeon can be quite positive that at the time of examination there is nothing wrong with the appendix, he dare not guarantee that it will not develop acute symptoms within a few weeks'. So what is the honest surgeon with any

consideration for his reputation, even if he hasn't a starving family, to do?

There are a very large number of useful skiagrams, photographs and charts throughout the book.

It is a book that we can recommend to the practising physician or surgeon and to the teacher.

ANUS, RECTUM, SIGMOID COLON. DIAGNOSIS AND TREATMENT.—By Harry Ellcott Bacon, B.S., M.D., F.A.C.S., F.A.P.S. 1938. J. B. Lippincott Company, Philadelphia and London. Pp. xxiv plus 855. With 487 illustrations. Price, 38s. Obtainable from Messrs. Butterworth and Company (India), Limited, Calcutta. Price, Rs. 28-8

WITHIN a generation proctology has attained an important position as a speciality in surgery. Dr. Bacon's book, to which Mr. Lockhart-Mummery contributes a foreword, is truly of the encyclopædic type and is expected to prove of value to proctologists and general surgeons alike, as a work of reference. The introduction by Dr. Wayne Babcock is cordial and appreciative and this book is described as the most complete and detailed work on proctology.

It is a book of considerable size containing 855 pages and 487 illustrations. There are altogether 24 chapters in this book. The earlier chapters deal with the anatomy, methods of examination, diagnosis and anaesthesia, and comprise 104 pages. The following chapters deal with separate pathological lesions such as cryptitis, anal fissure, pruritis ani and fistula-in-ano. Each section is complete in every detail and the differential diagnosis is particularly exhaustive and the operative technique is clearly described. The chapters on venereal diseases of the anus and rectum are worthy of note. Of ulcerations of the rectum and sigmoid mention must be made of chronic ulcerative colitis which is very clearly described. The chapters dealing with major surgery of the distal colon and rectum in case of malignant disease are written with great thoroughness. The management of colostomy is particularly praiseworthy.

We have gone through this book with both pleasure and benefit and feel sure that no general surgeon can afford to be without it. The subject-matter has been described throughout with conspicuous lucidity and precision. The illustrations are excellent and the printing and binding are praiseworthy. The bibliography is remarkably comprehensive and there is also a useful subject index.

P. N. R.

CANCER: ITS DIAGNOSIS AND TREATMENT.—By Max Cutler, M.D., and Franz Buschke, M.D. Assisted by Simeon T. Cantrell, M.D. 1938. W. B. Saunders Company, Limited, Philadelphia and London. Pp. viii plus 757. With 344 illustrations. Price, 45s. net

THE title of this book may appeal to a large section of the medical profession because the pressing problem of malignant disease deserves the dignity of separate treatment. It was, therefore, with some expectation that we approached the book, but we are constrained to state that we were disappointed. The illustrations are excellent but the supporting material is very meagre.

Radium is very much in the public eye at present and the laity cannot be blamed for believing it to be the only panacea for malignant disease. Statistics of radium therapy have their value but the important fact remains that carcinoma in accessible parts of the body can definitely be cured by adequate and early operative treatment. It is a statement which requires emphatic assertion. Telecurietherapy is admittedly an advance on the past, but sufficient evidence has already accumulated to indicate that the newer method of deep therapy by means of the 'continuously evacuated extra high voltage x-ray tube' is destined to supplant radium in a great measure, particularly in the case of the deeply-seated inaccessible new growth. It is regrettable that in the chapter on radiation therapy there is no mention of this potent therapeutic agent. There is

also no mention of the good results obtained by means of the low voltage contact therapy (Chaoul therapy). In a book of this character, such glaring omissions would be sufficient condemnation.

The authors have taken pains to explain that the special purpose of this work is to make accessible to the reader a critical evaluation of the pertinent facts in the diagnosis, prognosis and treatment of cancer. Under the semi-popular title of cancer, the authors have included sarcoma and neoplasms of bone although it is not customary to do so. It is, however, clear that cancer is a term which is readily understood by the non-medical reader. Nevertheless, it has to be admitted that the object of the authors is laudable, though difficult of attainment because interpretation of clinical data demands not merely experience but also judgment. For example, the authors have ascribed the remarkable freedom of the Jewish people from carcinomata of the penis and uterus to the influence of 'inherent racial susceptibility'. A more rational explanation would point to improved sex hygiene in the male and consequent freedom from chronic cervicitis in the female. It may be remembered that chronic infection and lymphatic stasis are not unimportant predisposing factors in carcinogenesis. Finally, it may be asked if the subject of carcinogenesis may rightly be excluded from a volume which deals exclusively with carcinoma?

It is evident that much hard work has gone into the making of this book but unless the defects are remedied it is not likely to be of use to those for whom it is intended. We are afraid there is very little use for a handsome expensive album on malignant disease.

P. N. R.

A TEXTBOOK OF SURGICAL PATHOLOGY.—By C. F. W. Illingworth, M.D., F.R.C.S. (Edin.), and B. M. Dick, M.B., F.R.C.S. (Edin.). Third Edition. 1938. J. and A. Churchill Limited, London. Pp. viii plus 727, with 299 illustrations. Price, 36s.

SINCE its first publication in 1932, this book has been well known to the students of special pathology, particularly those going up for the Fellowship examination in surgery. The subject of surgical pathology is by no means an easy one and the task of writing a textbook on such a subject is very arduous indeed. In getting up this volume the authors have collected data not only from the operating theatre and post-mortem rooms, but from pathological research laboratories as well. In spite of the frank warning 'presuming a certain knowledge of general pathology on the part of our readers' the first four chapters, namely those on inflammation, wound infection, surgical shock and burns, are so lucidly written that even a busy general practitioner will find the reading extremely interesting and containing an epitome of the most up-to-date ideas and information.

Of the specific infective diseases, tuberculosis, actinomycosis and hydatid disease have been dealt with in detail in separate chapters. In the chapter on tumours one finds all the latest information on the researches on the genesis, onset, propagation and spread of carcinomatous growths, and the classification of tumours is really admirable in its simplicity. The rest of the 26 chapters cover the diseases of the bones, joints, and the different systems of the body of which the pathology of the diseases of the brain, spinal cord, pituitary and adrenal glands are worthy of special note.

In connection with diseases of the female generative tract, an extremely rare tumour like arrhenoblastoma has been mentioned. The photographs of the specimens are from the museum of the Royal College of Surgeons and the photomicrographs of sections from the cabinet gallery of the Royal College of Physicians, Edinburgh; they constitute a very valuable integral part of the book, not only for the text but for reference as well.

After going through this volume one is just a bit disappointed that the authors thought fit to leave the diseases of the eye, ear and nose completely out of

their scope. Considering the reputation and ability of the authors the inclusion of chapters on these subjects in future editions of this book will be welcomed by the student, as well as the pathologist.

K. P. B.

ESSENTIALS OF PATHOLOGY.—By L. W. Smith, M.D., and E. S. Gault, M.D. 1938. D. Appleton-Century Company, Incorporated, New York and London. Pp. xxi plus 886, with numerous plates. Price, 35s.

THERE are many well-known books on general pathology that have gone through a number of editions and have survived their original authors. We are not quite sure whether this practice of reissuing new editions of old books is a good one and whether it is not better for the new generation to make a completely fresh start and, unhampered by the earlier tradition, produce an entirely new book. Such a procedure does not mean that full use should not be made of older teaching and other books, even to the extent of quoting long passages or reproducing illustrations.

There is in the volume under review much that is new in the method of presentation of the subject. It is eminently practical and close touch with clinical medicine is maintained—in fact forced upon the student—by the inclusion of at least one case history with each pathological picture that is drawn. It is such a natural procedure that one does not at first realize that it is not the usual method in textbooks of pathology. In later years, when one turns to one's textbooks on pathology, one automatically supplies the clinical picture from personal experience, but when the student first learns pathology it is liable to be as a subject apart, for at that period of his career he has practically no clinical experience on which to draw. There is a wealth of illustrations, most of which mean something, and this is not always the case in textbooks. Where it seemed advisable, drawings are substituted for photographs, but the majority of the illustrations are the latter. Most of the drawings are in colour and these are well executed, clear but not too diagrammatic.

A number of pages are devoted to parasitic diseases, of protozoa and helminths. The authors excuse this on the grounds that travel is so rapid in these days that nearly all diseases are cosmopolitan. Is it just 'insularity', which is incidentally a much more pronounced trait in the United States of America than amongst the island-dwellers of western Europe, or just modesty, that makes them overlook the possibility that not only may the parasitic diseases go to Mohammed but the Koran may find its way to the lands where these parasitic diseases flourish?

The reader with a poorer vocabulary will find it difficult to get used to some of the American applications. For example, 'gross'—a good old English word—is used as a substitute for 'naked eye', admittedly a clumsy compound adjective, in the sense 'naked-eye appearances'. But when one reads 'These nodules may be seen *grossly* on the surface of the spleen', it is a little bit of a shock.

We noticed a few minor mistakes, such as the reference in the caption of figure 488 to figure 482, when obviously 481 was intended, but otherwise the book seems to have been produced with the greatest care.

Finally, we should like to congratulate the publishers on their format. When deciding on the size of a volume publishers and authors should make up their minds whether the book will be read mostly in the hand or on a table, if the latter then it must not be too thick and it must open flat, but a little freedom can be exercised in the size of the page. The present volume with its large page, $8\frac{1}{2} \times 11\frac{1}{2}$ inches, is an ideal book to read on the table or laboratory bench.

It is a book that we can unhesitatingly recommend to physicians, students, and pathologists, particularly teachers of pathology.

THE NEW INTERNATIONAL CLINICS.—Edited by Giorgio M. Piersol, M.D. Volume III. New Series one (old 48th). 1938. J. B. Lippincott Company, Philadelphia and London. Pp. iv plus 341. Illustrated. Price, £2 10s. per set of 4 volumes. Obtainable from Messrs. Butterworth and Company (India), Limited, Calcutta

THIS volume of the *New International Clinics* contains a number of important and useful articles. The position of the practitioner who may not have all the latest appliances for diagnosis and treatment at his disposal is appreciated by many of the writers, so that these quarterly publications should have a wide appeal.

There are two articles on obesity, both give the same message, namely, that the only way to reduce a patient's weight is by making him restrict his, or more often her, diet. One writer insists that a rigid diet should be prescribed and the patient allowed no licence; the other considers that it is better to make the patient understand the principles of dietary and above all appreciate the seriousness of the disease (obesity).

This latter writer, Dr. Fred. M. Hanes, considers that obesity is no matter for joking, though he quotes one or two trite sayings, such as that the pleasures of life are always illegal, immoral, or make you fat and that there are three stages of obesity, the enviable, the laughable, and the pitiable.

There is an article on the testing of liver extracts, which is interesting but rather discouraging. Little progress has been made in testing these outside the wards of a hospital. The partial success of Rhoads and Miller with pigs on a 'black-tongue' diet is recorded, but there is no reference to Wills's work with monkeys. The writers conclude that 'such anemic swine may eventually prove of use as test animals'. [We might remind readers that this is not a clinical article.]

A HANDBOOK OF MIDWIFERY: FOR OBSTETRIC DRESSERS, PUPIL-MIDWIVES AND MIDWIVES.—By Sir C. Berkeley, M.A., M.C., M.D. (Cantab.), F.R.C.P. (Lond.), F.R.C.S. (Eng.), M.M.S.A. (Hon.), F.C.O.G. Tenth Edition. 1938. Cassell and Company, Limited, London. Pp. x plus 633, with colour frontispiece and 81 illustrations in the text. Price, 8s.

THE tenth edition of this popular book will be as widely used as ever by nurses sitting for the C.M.B. examination and as a book of reference after qualifying. The rather detailed nature of its contents, although rather more than will be required for the examination, will be very welcome to the midwife with a difficult case on her hands.

After reading *The Abnormal in Obstetrics* by the same author in collaboration with Victor Bonney, one was surprised to find that the latest ideas as set forth in that volume were very often not mentioned in the *Handbook of Midwifery*, older methods being given instead. For instance, the treatment of eclampsia is dealt with in a very different manner in the two books. Surely, the most advanced lines of treatment should be advocated for midwives and obstetricians alike!

However, there is no doubt that the book is a very sound little volume. Its small size makes it handy for fitting into the midwife's bag, although this advantage is somewhat outweighed by the small print used.

G. P. C.

HANDBOOK FOR MIDWIVES AND MATERNITY NURSES.—By Mary Mayers, S.R.N., S.C.M. Second Edition. 1938. Baillière, Tindall and Cox, London. Pp. xii plus 476. Illustrated. Price, 8s. 6d.

THIS textbook has proved its popularity by requiring a second edition only 20 months after the first. There is a lot to be said for a textbook for midwives being written by a member of the nursing profession. Miss Gemmel, as a sister tutor, probably has a closer insight into the difficulties and the best method of teaching midwives than can be attained by a member of the medical profession. This advantage probably

more than counterbalances the various unimportant errors which crop up in various places in the text.

The fairly detailed anatomy and physiology is good. Oestrin and progesterin are mentioned, but a short paragraph on their functions would have been appropriate. Miss Mayers states that vitamin E is usually prescribed in sterile matings. Perhaps so, but it is of very doubtful value, whereas the importance of vitamin E as a prophylactic against abortion is not mentioned.

When describing the disadvantages of premature rupture of the membranes the author stresses in two places in the book that slow-dilatation and delayed labour result. This old teaching has been disproved time and again, although, of course, it holds true where the premature rupture is due to some disproportion. It is but to be expected that the old vice of the nursing profession of giving aperients to patients prior to operation should find a place in this book. Why must patients have their vitality lowered just when they need it most?

In spite of such criticism the general impression gained is that the book is very sound, is simply and attractively written, well illustrated and is printed in large clear type.

G. P. C.

DIETS FOR DIABETES ARRANGED IN MENU FORM.

—G. E. Beaumont, M.A., D.M. (Oxon.), F.R.C.P., D.P.H. 1938. J. and A. Churchill, Limited, London. Pp. vi plus 49. Price, 2s.

This little book seeks to present diets for diabetics in menu form. It starts with diet no. 1 which contains as little carbohydrate as 7.5 grammes, protein 15.2 grammes and fat 9.6 grammes, yielding a total caloric value of 178 only! Even as we proceed to diet no. 8, we still find the carbohydrate content to be as low as 50.5 grammes, yielding a total caloric value of 1,398 only, which we consider to be quite insufficient for a man of average height and weight doing ordinary work. While there is no doubt that the presentation of these various diets in suitable menu form will offer to the patient an easy method of selecting meals which will suit both his appetite and taste, we have our doubts as to how far, in view of the present-day dietetic principles of treatment, these diets would prove to be useful.

J. P. B.

BIOCHEMISTRY FOR MEDICAL, DENTAL AND COLLEGE STUDENTS.—By Benjamin Harrow, Ph.D. 1938. First Edition. W. B. Saunders Company, Philadelphia and London. Pp. 383. Illustrated. Price, 17s.

The subject of biochemistry has during the last few years become of considerable importance in the practice of medicine. In fact, the present-day activity in biochemistry appears to be as varied as it is intensive, and some of the most sensational successes in recent times have been in the field of vitamins, hormones and enzymes.

It is therefore essential for modern students of medicine to be thoroughly acquainted with the main principles of biochemistry and the present volume appears to be an excellent one to help them in getting a clear insight into the subject. The book includes the latest developments in biochemistry, more particularly in the region of vitamins (described in chapter 8) and hormones (described in chapter 23).

The book covers more than the usual requirements of the student, and would, we believe, be of great help to them in pursuing their studies in the subject.

J. P. B.

APPLIED ANATOMY: FUNCTIONAL AND TOPOGRAPHICAL.—By R. H. Miller, M.D. 1938. Henry Kimpton, London. Pp. 484. Illustrated with 55 engravings and 16 coloured plates. Price, 30s.

This book is, in the reviewer's opinion, an excellent production because it describes on a regional basis the

essential anatomical points of the body structures that a practising physician or surgeon needs to remind himself of. As it is divorced from the amount of detail that the ordinary textbook of anatomy contains, it will enable the busy doctor rapidly to brush up the necessary information on any special problem with which he may be faced in his daily round.

This book will not be of great use to students still familiar with detailed anatomy except perhaps as a means of rapid revision to those sitting for their final examination, but it is essentially a book for the practitioner of some years' standing in whose memory the thousands of anatomical details are becoming dim.

It is copiously illustrated and a large proportion of the figures have been borrowed from Gray's anatomy.

CATALOGUE OF LEWIS'S MEDICAL AND SCIENTIFIC LENDING LIBRARY. Part I: Authors and Titles. 1938. H. K. Lewis and Company, Limited, London. Pp. viii plus 550. Price, 16s. (To Subscribers, 8s.)

Lewis's Library is a tradition amongst medical students in England, a tradition which they often maintain throughout their medical careers. Not infrequently have we heard a student who found it difficult to uphold his particular hospital pointing out its proximity to Lewis's as one of its main advantages. The library was founded in 1848 and so is not far off its centenary.

The subscriptions to the library are scaled according to the number of books taken out at a time, and vary from 7s. for one volume for three months to £15 for thirty volumes, for a year. A small deposit is asked from foreign subscribers.

The Catalogue is issued in two volumes, part I being 'authors and titles' in which the arrangement is alphabetical according to the name of the first author. The second part will be a classified index of subjects.

The Catalogue contains the names of 20,000 books on medical and allied scientific subjects. It is of course essential for subscribers who live any distance from Gower Street to possess these books, and librarians will find them very useful as books of reference.

DISPENSARY LABEL BOOK. Printed at The Merchants Press, 85, Nainappa Nalck Street, Park Town, Madras. Price, Re. 1

This book is what its name suggests. It consists of printed labels for dispensary use; these can be cut out and pasted on bottles. Doses are given in smaller print.

There are in this book nearly a thousand different labels.

The book should prove very popular amongst those who like to keep their dispensaries neat and tidy.

The only improvement that suggests itself to us is the perforation of the pages so that the labels could be torn out easily.

Abstracts from Reports

ANNUAL REPORT OF THE ALL-INDIA INSTITUTE OF HYGIENE AND PUBLIC HEALTH, CALCUTTA, FOR THE YEAR 1937

The institute has till now produced four batches of Diplomates in Public Health. An enquiry was instituted with a view to ascertaining how far India had made use of the graduates of the institute and how they were being employed. A request was made to the ex-students to supply information regarding their employment and the nature of their duties. The response shows that about two-thirds of the graduates, which the institute has produced since 1934, hold official positions, but that less than half are engaged in public health or research work. Most of the employees are government servants. Local bodies and other authorities who are mainly responsible for the

administration of public health, employ only a small number.

Epidemic dropsy.—The mode of causation of epidemic dropsy has so far remained unknown and treatment is also unsatisfactory. For the last three years, researches have been conducted at the institute on its aetiology. Many of the current theories have been investigated critically, and the work done seems to have incriminated mustard oil as the medium by which the toxic substances responsible for the disease are taken into the human body. Attempts are now being made to isolate these toxins in the oil and to study their chemical and pharmacological properties. Methods for detecting the presence of these substances in suspected samples of oil are also under investigation; it is hoped that the problem of its causation will shortly be solved.

Forecasting cholera epidemics.—A method of forecasting cholera epidemics which proved useful for the control of the disease has been applied by the institute, with respect to certain areas in Bengal, not inappropriately considered to be the home of cholera.

A study has also been made of the causes of the periodic rise in malarial incidence in certain endemic areas in Bengal. It has been found that the sudden exacerbations in malarial incidence, which usually take place every five or six years, are in all probability associated with unusual rainfall in the dry months, especially February and March. If the rainfall is markedly high in the dry months even when the total annual rainfall remains unchanged, the incidence of malarial fever may be expected to be higher than in other years. The work is of special interest as results are likely to be of great assistance in the organization of anti-malaria campaigns.

Treatment for black-water fever.—Black-water fever has hitherto defied treatment to a large extent. Researches conducted at the institute during the past few years have not only indicated the manner in which black-water fever is caused, but have also helped in the elaboration of a new line of treatment which has so far given encouraging results.

In kala-azar, investigations are now being made into the problem of susceptibility to the disease. Kala-azar has not yet been experimentally produced in man, but man suffers from it in nature. This, it is thought, is probably due to the fact that infection results only when resistance is lowered.

Maternal mortality investigations.—Investigations have also been made into the causes of maternal deaths in Calcutta. Over 90 per cent of these deaths, it has been found, were preventable, and the conclusion was reached that maternity need not be attended with such grave risks if the expectant mother could be given adequate medical supervision during pregnancy, at the time of delivery and for a few weeks following confinement. The enquiry has also revealed that one of the important causes of maternal deaths is 'pregnancy anaemia'. Investigations are in progress for finding out the responsible causal factors and the best method of treatment.

A model maternity and child welfare centre attached to the institute gives practical demonstrations of how maternity and child welfare work can be carried out under Indian conditions. The staff of the clinic, under the supervision of the Professor of Maternity and Child Welfare, tries to get in touch with pregnant women by house to house visits and to teach them healthy ways of living. Periodical examinations are made to ascertain whether any abnormal conditions exist, the babies are delivered in the homes in all normal cases, the mothers and infants are looked after and further examinations and treatment are given where necessary.

A nursery school is attached to the clinic, admission being confined to children between the ages of 2 and 5 years. A specially trained member of the staff teaches them healthy habits, discipline and sociability, while games are arranged for the development of their minds and bodies. Through the activities of the clinic and by means of special lectures and instructions in

mothercraft, the centre helps to create health consciousness amongst women.

Decline in infantile mortality.—Analysis of figures for infantile mortality shows a decline in the rate within recent years, although, as compared with those of Great Britain, the figures are still high. The problem of infantile mortality is closely related to that of infant nutrition. A beginning has been made on research into this subject.

The Nutrition Department has been conducting diet surveys amongst certain classes of people in Bengal and Assam. The diet of the Assamese coolie has been found poor both in quality and quantity, and particularly deficient in proteins, fats, minerals and vitamins. The heights and weights of Assamese children fall much below the normal and also below that of well-to-do groups. The diet of well-to-do residents in Calcutta has been found to compare favourably with that of European standard except that it contains an excess of fat.

The trend of population growth in India has lately come under investigation in the Statistical Department of the institute. The studies made show that 'measures directed towards the reduction of mortality will also help to lower the birth rate'.

Tuberculosis and industry.—In the tuberculosis enquiry carried on in the institute, a study is being made of the relationship of certain industries to the disease. India is becoming more industrialized and urbanized and this new factor has been held responsible for a marked increase in the incidence of the disease. The jute industry is particularly being studied to find out how far it contributes towards the spread of tuberculosis.

The work so far conducted reveals that the majority of the cases of tuberculosis in jute mills are found among the poorer labourers living in ill-ventilated and insanitary tenements. The fact that susceptible persons are migrating to take up work in these industrial concerns is also held to be to some extent responsible for the severe type of tuberculosis prevalent amongst the mill workers.

ADMINISTRATION REPORT OF THE DIRECTOR OF MEDICAL AND SANITARY SERVICES, CEYLON, FOR 1937

THE most prevalent general diseases of hospital in-patients were rheumatism, intestinal disorders (diarrhoea and enteritis), bronchitis, and pneumonia. Year by year the number of patients who seek hospital treatment for cancer is increasing.

The incidence of plague compared with the average for the previous five years (57) has decreased to 29 during 1937. Of these, 20 cases were of the bubonic variety and nine septicæmic.

There were no cases of cholera during 1937 in the island.

There were two cases of smallpox in February 1937, and both these cases were among new arrivals from India.

One hundred and thirty-five cases of diphtheria compared with 103 cases in 1936 were reported during the year with 21 deaths, giving a fatality rate of 15.55 per cent.

Seven thousand, two hundred and forty-eight cases of measles compared with 2,775 in 1936 were reported during the year with 26 deaths giving a fatality rate of 0.35 per cent.

The actual prevalence of enteric fever cannot be judged from hospital admissions since many cases resort to ayurvedic treatment and the majority of cases probably are not notified. The number of registered deaths does not indicate the actual mortality from this disease, as some deaths from enteric are undoubtedly included amongst those reported as due to pyrexia. There were 13,918 deaths due to pyrexia in 1937 as against 14,520 in 1936. Two thousand, six hundred and twenty-nine cases were notified in 1937 as compared with 2,503 in 1936, with 502 deaths, giving a fatality rate of 19.09 per cent.

Three thousand and ninety-three cases or 51.0 per cent of the total number of dysentery cases were stated to be amœbic, 1,564 cases or 25.9 per cent bacillary, and the balance 1,380 or 23.1 per cent undefined. These figures, however, are not of great value since the distinction was often made on clinical grounds.

Tuberculosis of the lungs.—The following table shows a comparison between the figures for 1937 and the figures for the previous four years:—

	1933	1934	1935	1936	1937
Hospital cases ..	4,229	4,278	4,851	4,449	4,554
Hospital deaths ..	1,108	1,126	1,382	1,054	1,169
Total number of deaths registered for the island ..	3,118	3,091	3,387	3,167	3,145

Leprosy.—During the year 1,292 cases with 84 deaths, as against 1,253 cases with 74 deaths in 1936, were treated at Government hospitals including the two asylums which are maintained in the island for the segregation of lepers.

During the year 30,411 children in 208 schools were examined and 16 cases detected of whom eight had definite lesions and eight indefinite lesions.

The total area covered by the survey was about 2,000 square miles with a population of over 600,000.

With the organization of the Malaria Control and Health Scheme the control of yaws has been placed on a more satisfactory basis. Each of the field medical officers and medical officers of health is responsible for the control of the disease in his area. Every case in the area is put on a card, inspected and re-inspected every six months, and necessary treatment given. Villages, in which cases are found, are carefully inspected half-yearly for detection of new cases.

HYGIENE AND SANITATION

Public health work continues to make steady progress. The Malaria Control and Health Scheme which was launched during the latter part of 1936 was extended during 1937 to include the whole of the North-Western Province, the Matale and Kandy Districts of the Central Province, Province of Sabaragamuwa with the exception of Kolonnua and Kukul Korales, Mannar and Mullaitivu Districts and the Tenmaradchi and P. . . . divisions of the Northern Province, Hambantota Districts and Gaugaboda pattu in the Galle District of the Southern Province, certain areas in the Batticaloa District of the Eastern Province, one chief headman's division of the Province of Uva, Hurulu, Kalagam palatas, and Tammankaduwa division of the North-Central Province, and three chief headmen's divisions in the Western Province.

General sanitation has received the same attention as in previous years. The two important items under this head are: control of soil pollution and the provision of protected water supplies.

In the control of soil pollution during the year 4,672 bucket latrines were constructed in urban areas as compared with 3,687 in 1936; 16,619 deep pit latrines in rural areas as compared with 13,639 in 1936; 179 bored-hole latrines as compared with 312 in 1936; 322 mound latrines as compared with 263 in 1936 making a total of 21,792 as compared with 17,901 in 1936.

In order to hasten the construction of latrines a five-year programme has been formulated for areas under sanitary assistants (inspectors) and every effort is being made completely to sanitize villages. There still continues to be a good deal of indifference on the part of villagers to construct latrines.

In regard to the provision of protected water supplies during the year 281 new public wells and 4,215 new private wells were constructed, and 2,794 wells were improved.

The annual grant for the construction of wells in rural areas is inadequate to meet the problem in a satisfactory manner. When village committees construct wells out of their own funds they prefer to build wells for bathing purposes rather than for drinking

purposes. Till such time as an adequate number of protected wells are provided, the people are being educated to boil their drinking water.

Housing in urban areas is under control and small housing schemes have been carried out. In rural areas all that has been done has been in relation to peasant colonization schemes in connection with which dwellings are being constructed in accordance with two type plans supplied by the department; one for the married and the other for the unmarried settler. In the construction of these dwellings each settler is given a government subsidy.

On estates regular inspection has been carried out on labourers' lines and government requirements were met with in the case of 59,067 rooms as compared with 49,351 in 1936.

Maternity and child welfare work continues to receive popular support. The work has been carried out at 207 centres as compared with 77 in 1936; at which 8,395 clinics have been held as compared with 4,513 clinics in 1936; with a total attendance of 39,841 expectant mothers as compared with 17,393 in 1936, 88,479 infants as compared with 29,563 in 1936, and 39,637 pre-school children as compared with 18,611 in 1936. These increased numbers are due to the large number of field medical officers and associated staff who have been appointed. The infant mortality shows a reduction from 166 in 1936 to 158 in 1937 and the maternal mortality rates from 21.6 in 1936 to 19.9 in 1937. In limited areas where intensive work is being done with an adequate staff of public health nurses and midwives the reduction in mortality rates is very encouraging.

On school health work depends the future of the public health work of the country. A good deal of attention has been paid to the health of the school child and the work is being appreciated by all concerned with the result that work is receiving more co-operation.

The hookworm campaign was carried out with more intensity and 2,163,373 treatments were given as compared with 1,855,572 in 1936 and 1,401,962 in 1935.

The leprosy survey, which had completed and organized its work in the Eastern, Western, Sabaragamuwa, and Southern Provinces, extended its work to the North-Western Province, and continued follow-up work in the former provinces.

An island survey of filariasis was undertaken and is in progress. Control work in a demonstration area in Dewameddi Hatpattu in the North-Western Province is being undertaken, and action is being taken for the removal of the pistia plant throughout the island.

Health work under Urban District Councils is being carried out satisfactorily. One council continues to have its own Medical Officer of Health who is a private practitioner and another council nominally has the departmental Medical Officer of Health in an executive capacity without getting him to function as such.

Health Unit work which was inaugurated in 11 areas is now the type of work that is being carried out in the major part of the island and continues to be satisfactory in every respect.

REPORT OF THE SUDAN MEDICAL SERVICE FOR THE YEAR 1937

YELLOW FEVER

The examination of liver sections from fatal cases of obscure pyrexia.—During the year eight viscerotome specimens of livers were examined histologically but in no instances were the morbid changes suggestive of yellow fever.

Mouse-protection tests.—In March 1937, Dr. G. M. Findlay of the Wellcome Bureau of Scientific Research, London, visited the Sudan, and collected a further series of human and animal sera from the Nuba Mountains and Sennar districts.

(a) *Human sera.*—The results, which will be published in full by him, confirm completely the findings

of last year. The high infectious rate (70 per cent and over) in the Kau district is still noticeable as is also the apparent rural distribution of the virus, and a striking difference in the percentage of positive sera from adjacent and apparently similar districts.

The mouse-protection test has also been carried out on the sera of a number of cases of obscure febrile jaundice. Of 34 sera nine have been positive and 25 negative. Little significance can be attached to a positive result in these cases unless a previous test (at an early stage of the illness) has been negative. In three cases in Malakal it has been possible to test the serum twice in this fashion, and the results are suggestive. Blood taken on the 10th day of illness was negative in all three cases. A second sample taken 12 days later was negative in one case, but in the other two it protected three out of six mice used in the test—a positive result, which has developed during the course of the illness.

The sera of five persons who visited Kau during the rainy season in 1936 were also tested by Dr. Findlay and all but one were positive. Two of these positives are particularly interesting—a British medical inspector whose blood was known to be negative a year previously and an assistant medical officer from the northern Sudan, posted to Kau in 1936. They both had an attack of fever at the same time in Kau. It was noted that the fever was not influenced by atabrin, and that a few evenings previously both had been badly bitten by mosquitoes while sitting out talking to local notables.

These results suggest that during the last two years there have been at least three human infections with the virus of yellow fever.

(b) *Animal sera*.—In the 1936 report it was mentioned that immune bodies had been demonstrated in two cows from Kordofan, and in one monkey.

During his tour this year Dr. Findlay obtained sera from wild and domestic animals in Kau. Among the latter, immune bodies were found in four out of 20 cows, two out of five dogs, and three out of 11 pigs. No positive sera were obtained from any of the wild animals from Kau, although numbers were tested, including ground squirrels, rats, monkeys, lizards, bats and mongoose.

An attempt was made in London to infect six gerbils, sent from the Sudan, with yellow fever, but these animals proved completely resistant to both neurotropic and viscerotropic virus intracerebrally.

Mosquito survey.—This is considered in the entomologist's report, but mention may be made here of the discovery of *Aedes* breeding in 'tebelidi' trees in entirely rural surroundings, two miles from the nearest human habitation.

Correspondence

INHIBITORY INFLUENCE OF CHRONIC AMOEBIASIS ON IMMUNITY AGAINST BACTERIAL INFECTION

To the Editor, THE INDIAN MEDICAL GAZETTE

SIR,—Some years ago an European boy of about six years was brought to us for treatment of scabies. On culture of pus from one of the pustules, *Staphylococcus aureus* was obtained. A course of 5 injections of autovaccine was given, apparently without any effect. New pustules were developing during the course of treatment by autovaccine. Repeated culture of pus showed the same *Staphylococcus aureus*. There was no previous history of dysentery. There was no bowel complaints except occasional constipation. Yet we examined the stool of the boy and we were surprised to find the presence of vegetative forms of *Entamoeba histolytica*. On giving a course of only three injections of $\frac{1}{2}$ grain

of emeline, the scabies* disappeared quickly. This finding strongly suggested to us that probably chronic amoebiasis had an inhibitory influence on the formation of antibodies in the system against bacterial infection. Since this case we encountered at least 15 other cases of chronic staphylococcal eczema, streptococcal pustules on the fingers and palms which resisted all treatment by autovaccine and local medication. On examination of stools of all these cases *Entamoeba histolytica* either in the vegetative or cystic forms was found. A combined treatment with emetine and autovaccine invariably cured these cases. Some had relapse and re-examination of stool revealed the presence of *Entamoeba histolytica* cysts. Evidently amoebiasis was not altogether cured by treatment. Intensive course of treatment with emetine and stovarsol finally cured those cases permanently. These observations lead us to believe that the presence of amoebic infection has a definite inhibitory influence on bacterial immunity. Chronic skin diseases due to staphylococcus are often encountered among apparently healthy people of this country, particularly those living in the villages. Chronic amoebiasis is an extremely common condition among the people of this country and it is our definite opinion that amoebiasis plays a great rôle in the chronicity of bacterial skin infection (excluding fungus) by exerting an inhibitory influence on the natural formation of immune bodies.

Yours, etc.,

H. GHOSH, M.B., M.S.P.E. (Paris),
Director.

DEPARTMENT OF BACTERIOLOGY,
INDIAN INSTITUTE FOR MEDICAL
RESEARCH, CALCUTTA.

* [Note.—Our correspondent apparently means staphylococcal infection secondary to scabies.—EDITOR, I. M. G.]

A NOTE ON THE DESTRUCTION OF MOSQUITOES CAUGHT IN THE MODIFIED VILLAGE MOSQUITO TRAP* DURING MONSOON

To the Editor, THE INDIAN MEDICAL GAZETTE

SIR,—During the monsoon the trapped mosquitoes are killed by putting the pot on a hearth which will raise the inside air temperature to 60°C. (140°F.). At this temperature the inside air is hot; the bottom of the pot is very hot, but the sides are merely warm. By this time all the mosquitoes will be found dead, and the pot is removed from the hearth. The whole operation takes about fifteen minutes using a moderate fire.

This method could be used any time or throughout the year, being available, quick and clean.

Yours, etc.,

RAMKRISHNA N. GORE, L.M.S.

COLSULANYDE IN QUINSY

To the Editor, THE INDIAN MEDICAL GAZETTE

SIR,—I wish to report the following case in your esteemed journal, and hope you will consider it.

R. B., aged 35, a mill-worker, called at this hospital with slight bleeding from the mouth on spitting, great difficulty on swallowing even semi-solid foods, and pain all over the mouth and head. He was running a temperature of 102°F. An examination of the throat revealed a left-sided 'quinsy' with marked congestion

* Gore, R. N. (1937). A Modified Village Mosquito Trap. *Indian Med. Gaz.*, Vol. LXXII, p. 674.

on the right tonsils also. On refusal of the patient for surgical treatment he was given on the first day 10 c.c.m. of 0.4 per cent 'Colsulanyde' (Crookes) intravenously and 2 tablets three times a day. Second day—marked improvement, but was given another injection and tablets by mouth. Third day—no fever, no bleeding, very little pain. Only tablets were given that day and next day the patient reported that he was completely all right.

The point of interest in this case was that no surgical treatment was done, and the only local treatment advised was salt gargle.

I wish to point out that I have tried this preparation of sulphanilamide in a series of cases of tonsillitis and allied conditions, and have found it very efficient.

Yours, etc.,

G. S. GOPALAN, L.M.P. (Madras).

A PROBABLE CAUSE OF THE DIFFICULTY OF TREATING CHRONIC AMOEBIC INFECTION IN THIS COUNTRY

To the Editor, THE INDIAN MEDICAL GAZETTE

Re: Article by Dr. H. Ghosh concerning the probable cause of the difficulty in treating chronic amoebic infection in your issue of January 1939.

SIR,—I have not known a single uncomplicated case of chronic amoebic dysentery fail to respond to the emetine bismuth iodide and yaten lavage treatment laid down by Dr. Manson-Bahr. Those cases which relapsed had definitely acquired a chronic bacillary dysentery infection as well, and a certain number of these cases undoubtedly had a further streptococcal infection. The bacillary infections were mainly Flexner and an intolerance for rice diet can be understood.

Yours, etc.,

C. E. R. NORMAN,
Chief Medical Officer,
South Indian Railway.

PRAWNS AS A POSSIBLE VECTOR OF V. CHOLERÆ

To the Editor, THE INDIAN MEDICAL GAZETTE

SIR,—I have read Dr. K. P. Kundu's article on 'Prawns as a possible vector of *V. cholera*', published in the October 1938 issue of your *Gazette*, with keen interest. Heiberg (1935, 1936) as a rejoinder to the publication by Gardner and Venkatraman (1935) showed that the vibrios could be grouped into 6 by fermentation reaction of three sugars, mamose, saccharose and arabinose, as Gardner and Venkatraman were of opinion that vibrios could not be grouped by biochemical reactions. Taylor, Pandit and Read (1936, 1937) later on showed that Heiberg groups could be increased by one more. Gardner and Venkatraman on analysis of 'O' antigens of vibrios by serology, could group the vibrios into 6 'O' sub-groups. We could group the vibrios sharply into two groups, one could group the vibrios sharply into two groups, one by typical cholera vibrio, others non-cholera vibrio, by inhibition or fixation of specific cholera bacteriophage type 'A', a finding similar to that of Bruce-White (1936). Heiberg group I, Gardner and Venkatraman 'O' sub-group I and inhibition group I (unpublished) all include the typical *Vibrio cholera*, Inaba or Ogawa type. While the latter two groupings never include any non-cholera vibrios, Heiberg group I includes these vibrios besides the typical vibrio cholera, Inaba or Ogawa. Heiberg group II does not include the typical *Vibrio cholera* (*loc. cit.*) and when Dr. Kundu showed that typical *Vibrio cholera* of Heiberg type II were isolated from prawns, a suspicion arises about the

validity of the tests employed, biochemical and serological. The vibrios isolated from the prawns may share the 'H' antigen to the full titre of a typical cholera vibrio but that does not mean that they share the same 'O' antigen of a true cholera vibrio, Inaba or Ogawa. Now that the analysis of the 'O' receptor of typical cholera vibrio is complete by Bruce-White (1936a) and the antigen is shared by no other vibrios except cholera, mistakes of declaring a vibrio as typical cholera vibrio should not be committed any longer. On account of this mistake, the validity of much past research on cholera is even now disputed. Dr. Kundu's vibrios isolated from prawns A and B should be subjected to a thorough 'O' receptor analysis before they could be identified as typical cholera vibrio, Inaba or Ogawa. In view of the above consideration I do not like to comment on his summary of conclusions.

ANTI-TETANUS SERUM

To the Editor, THE INDIAN MEDICAL GAZETTE

SIR,—The prices quoted for anti-tetanus serum in the paper on 'A Study of Treatment of Tetanus Based on a Review of 38 Cases for the year 1932-1937' in your January issue are apparently those charged for serum of continental origin.

I have recently found that equally efficacious serum is obtainable at a much cheaper rate from a well-known firm of English manufacturers.

This may be of interest to your readers.

Yours, etc.,

A. B. C.

Service Notes

APPOINTMENTS AND TRANSFERS

COLONEL F. F. S. SMITH to be A. D. M. S., Peshawar District. Dated the 17th December, 1938.

Colonel D. F. Murphy, M.C., to be O. C., I. M. H., Secunderabad. Dated the 12th December, 1938.

Colonel N. S. Sodhi, on return from leave, resumed his duties as Inspector-General of Civil Hospitals, Burma, vice Lieutenant-Colonel J. Findlay, on the forenoon of the 27th January, 1939.

Lieutenant-Colonel Philip Verdon, permanent District Medical Officer and Superintendent, Government Headquarters Hospital, Guntur, and Acting Superintendent, Government Ophthalmic Hospital, Professor of Ophthalmology, Medical College, and Medical Officer, Civil Orphan Asylum, Madras, to be Superintendent, Government Ophthalmic Hospital, Professor

of Ophthalmology Medical College and Medical Officer, Civil Orphan Asylum, Madras, with effect from the 15th November, 1938, *vice* Lieutenant-Colonel R. E. Wright, C.I.E., I.M.S., retired.

Lieutenant-Colonel L. F. Brandenburg to be Officiating A. D. M. S., Madras District. Dated the 30th November, 1938.

Lieutenant-Colonel N. J. Gai to be O. C., I. M. H., Jullundur. Dated the 13th December, 1938.

Lieutenant-Colonel H. S. Rajan to be O. C., I. M. H., Jhansi. Dated the 10th December, 1938.

Lieutenant-Colonel N. S. Jatar, C.I.E., D.S.O., is on return from leave re-posted as Inspector-General of Prisons, C. P. and Berar, with effect from the 3rd January, 1939.

Lieutenant-Colonel P. D. Chopra has, on expiry of his leave, been placed on special duty in the Office of the Inspector-General of Prisons, Punjab, as Secretary to the All-India Inspectors-General of Prisons Conference, with effect from the 15th January, 1939.

Lieutenant-Colonel R. Hay is appointed Deputy Director-General, Indian Medical Service, with effect from the 16th January, 1939.

Lieutenant-Colonel J. Findlay, on relief, resumed charge as Inspector-General of Prisons, *vice* Lieutenant-Colonel I. S. Nalwa, on the forenoon of the 27th January, 1939.

On return from leave Major W. Lawie has been posted as Civil Surgeon, Agra.

Major A. K. M. Khan to be Officiating Surgical Specialist, Karachi. Dated the 2nd December, 1938.

Major H. S. Smithwick returned from leave and resumed charge of the duties of Civil Surgeon, Sholapur, with effect from the forenoon of 4th January, 1939.

Major K. S. Fitch, on the expiry of his leave, is appointed to be Civil Surgeon, Burdwan, *vice* Lieutenant-Colonel N. C. Kapur, granted leave.

Reverted to Military

Major W. F. Cooper from Port Health Office, Bombay, on 30th December, 1938.

Captain F. W. Whiteman from Bihar, on 5th December, 1938.

The Secretary of State for India has appointed to the Civil Branch of the Indian Medical Service the following Officers of the Indian Medical Service, with effect from the dates stated against their names:—

Central Government

Captain G. F. Harris. Dated the 26th February, 1938.

Captain F. R. Cawthorn. Dated the 8th April, 1938.

Captain G. P. Charlewood. Dated the 17th April, 1938.

Major B. M. Rao. Dated the 13th June, 1938.

Madras

Captain W. P. Lappin. Dated the 20th January, 1938.

Captain B. A. Porrit. Dated the 4th February, 1938.

Captain J. White. Dated the 24th May, 1938.

Captain G. B. Thomas. Dated the 13th June, 1938.

Bengal

Captain J. Brehner. Dated the 27th December, 1938.

Captain W. M. Niblock. Dated the 7th January, 1938.

Captain P. I. Franks. Dated the 11th April, 1938.

United Provinces

Captain B. J. Griffiths. Dated the 10th January, 1938.

Punjab

Captain C. F. Garfit. Dated the 22nd January, 1938.

Captain G. W. Miller. Dated the 1st February, 1938.

Major V. E. M. Lee. Dated the 25th February, 1938.

Assam

Captain D. Tennant. Dated the 21st January, 1938.

Captain S. Shone, transferred from the Military Department to Civil employ, to act as Junior Specialist in Medicine, Government General Hospital, Madras, with effect from the date of taking charge, *vice* Captain J. White.

Captain R. L. Haviland-Minchin is appointed to the Medical Research Department on probation for 2 years, with effect from the 21st November, 1938 (forenoon).

Captain F. McD. Byrn to be Medical Officer, Lawrence Royal Military School, Sanawar. Dated the 25th November, 1938.

Transferred to Civil

Captain F. C. Leach, to C. P. and Berar, on the 6th December, 1938.

Captain R. L. Haviland-Minchin, an Officer of the Medical Research Department, is appointed to officiate as Assistant Director, Central Research Institute, Kasauli, with effect from the 16th December, 1938 (afternoon).

Captain B. L. Taneja to be D. A. D. P., Presidency and Assam District. Dated the 23rd December, 1938.

Captain C. J. Hassett is appointed to officiate as an Agency Surgeon, with effect from the forenoon of the 10th January, 1939, and is posted to the North-West Frontier Province.

Captain F. C. Leach, attached to the Office of the Civil Surgeon, Nagpur, for training, is posted as Superintendent, Mental Hospital, Nagpur, with effect from the 16th January, 1939.

Captain J. White is posted temporarily to Howrah as Civil Surgeon.

Lieutenant (on probation) D. S. Wilson is reinstated to the Establishment 1st November, 1938, with seniority, 1st May, 1938.

LEAVE

Lieutenant-Colonel N. C. Kapur, Civil Surgeon, Burdwan, is granted leave *ex-India* for 8 months, with effect from the 7th November, 1938, or from any subsequent date on which he is relieved.

Lieutenant-Colonel L. S. Modi, Officiating Inspector-General of Prisons, C. P. and Berar, has been granted leave on average pay for 4 months, with effect from the 3rd January, 1939, preparatory to retirement.

Lieutenant-Colonel I. S. Nalwa was granted leave from the 27th January, 1939, to the 19th March, 1939.

Lieutenant-Colonel J. Rodger, O.B.E., M.C., an Agency Surgeon, is granted leave for 5 months and 7 days, with effect from the afternoon of the 9th January, 1939.

Major E. M. Sewell, leave *ex-India* for 10 months, with effect from the 1st February, 1939, or date of relief.

Captain J. J. Barton, Staff Surgeon, Quetta, proceeded on 9 months' combined leave *ex-India*, on the 29th November, 1938.

Captain H. A. Ledger, Surgical Specialist, Karachi, proceeded on 10 months' combined leave *ex-India*, on the 2nd December, 1938.

PROMOTIONS

Lieutenant-Colonels R. V. Morrison and J. Findlay have been advanced to the higher position of their rank, that is to the list of Lieutenant-Colonels specially selected for increased pay for ability and merit, with effect from the 31st May, 1937, and 14th October, 1938, respectively.

Lieutenant-Colonels S. S. Sokhey and W. C. Spackman have been advanced to the higher position of their rank, with effect from the 28th August, 1938, and 16th October, 1938, respectively.

Major to be Lieutenant-Colonel

B. P. Baliga. Dated the 17th December, 1938.

Lieutenants (on probation) to be Captains (on probation)

C. W. Greene. Dated the 16th May, 1938, with seniority from the 1st January, 1938.

G. A. Graham. Dated the 28th September, 1938, with seniority from the 1st May, 1938.

D. McC. Black. Dated the 28th September, 1938, with seniority from the 1st May, 1938.

J. G. Fife. Dated the 28th September, 1938, with seniority from the 1st May, 1938.

N. D. Jekyll. Dated 28th September, 1938, with seniority from the 1st May, 1938.

J. H. Briscoe-Smith. Dated 28th September, 1938, with seniority from the 14th August, 1938.

A. C. Glendinning. Dated the 28th September, 1938, with seniority from the 31st August, 1938.

G. C. Retz. Dated the 12th October, 1938, with seniority from the 1st July, 1938.

A. R. Woodforde. Dated the 12th October, 1938, with seniority from the 18th July, 1938.

R. D. D. Birdwood. Dated the 1st November, 1938.

R. Passmore. Dated the 2nd March, 1938.

RETIREMENTS

Colonel G. R. Lynn, D.S.O., retired on the 1st December, 1938.

Colonel W. J. Powell, C.I.E., K.H.S., retired on 17th December, 1938.

Lieutenant-Colonel B. Gale, who was on leave till the 30th January, 1939, retired from service, with effect from the 31st January, 1939.

RELINQUISHMENT

Lieutenant (on probation) D. S. Wilson relinquishes his probationary appointment, 8th December, 1938.

Notes

TREATMENT OF ASTHMA BY ORAL INHALATION

THE symptomatic treatment of mild to moderate attacks of asthma by means of oral inhalation of adrenaline solution of a strength of 1 in 100 is described by Graeser and Rowe in their original article (*Journal of Allergy*, 1935, 6 : 415). These authors describe the results of a series of 40 cases, clearly demonstrating the value of inhalation of adrenaline by the mouth for the prompt relief of asthmatic attacks. In most instances, the physiological effect occurred more rapidly than with hypodermic injection of the 1 in 1,000 solution; it was rarely slower. The authors, indeed, are so satisfied with the results of their work, that they feel the inhalation procedure may, in many cases, well supplant the use of adrenaline hypodermically.

Patients are instructed to place the nozzle of the atomiser just within the open mouth and to inhale deeply while creating a spray. The amount of inhalation varies for each patient, depending on the severity of the symptoms and the manner in which the atomiser is manipulated. Some patients find it necessary to inhale until cough occurs before relief is obtained. Therefore no definite dose can be given, and patients must learn from experience to estimate their own requirements. The treatment, until individual needs are ascertained, should proceed slowly, allowing one or two minutes to elapse between several deep inhalations.

Side effects, such as nervousness and tachycardia, which frequently follow subcutaneous injection of adrenaline, are rarely caused by inhalation of the 1 in 100 solution. Several patients, so susceptible to these disturbances that doses as small as 3 to 4 minims caused discomfort, were able to use the inhalation method with success. Some moderate dryness of the throat was experienced in about 30 per cent of the cases, but that was mitigated by rinsing the mouth with water immediately following inhalation.

A preparation of the requisite strength for this treatment is now made available by Burroughs Wellcome and Co. as 'Vaporole' solution of adrenaline, 1 in 100. Any atomiser delivering a fine, evenly-distributed vapour may be used, but for effectiveness and durability, no better apparatus could be selected than the 'Paroleine' atomiser, which has a stainless

steel delivery tube and is of exceptionally robust construction throughout.

'Vaporole' solution of adrenaline 1 in 100 is supplied in amber glass-stoppered bottles of 5 c.cm.

CARDIAZOL-QUININE-KNOLL

CARDIAZOL-QUININE combines rapidity of action with the highest possible degree of tolerability. The purpose of the combination is to complement the action of quinine in all indications requiring circulatory support. The cardiazol component increases the solubility of the quinine salts very considerably which explains why absorption of the remedy is exceptionally rapid, why it remains in the organism a very appreciable length of time and why it is able to attain a high concentration in the blood. Relatively large amounts of quinine in pure watery solution can be lodged in the organism by cardiazol-quinine injections (cardiazol-quinine ampoules, without additions of urethane, essential oils, etc.). The slight viscosity of the solution ensures satisfactory tolerance of the injections, assists rapid absorption and thus hastens the action.

The chief indications for cardiazol-quinine are influenza, pneumonia, bronchitis, rhinitis, tracheitis, anginous states, tonsillitis, typhoid, malaria, and tuberculosis; also heart disorders such as conductivity disturbances, arrhythmias; hyperkinesia, hyperexcitability and tachycardia. It is of great value in the enforced pauses of digitalis therapy and indicated also in primary feebleness of labour, febrile abortion, to induce labour and abortion and for the prophylaxis and treatment of post-operative pulmonary complications.

Publishers' Notice

SCIENTIFIC Articles and Notes of interest to the profession in India are solicited. Contributors of Original Articles are entitled to receive 25 reprints *gratis*; additional reprints can be obtained on payment. No reprints will be supplied unless contributors ask for them at the time of submitting their manuscripts.

Communications on Editorial Matters, Articles, Letters and Books for Review should be addressed to THE EDITOR, *The Indian Medical Gazette*, c/o The Calcutta School of Tropical Medicine, Central Avenue, Calcutta.

Communications for the Publishers relating to Subscriptions and Advertisements should be addressed to THE PUBLISHERS, *The Indian Medical Gazette*, P. O. Box No. 54, Calcutta.

Annual Subscription to 'The Indian Medical Gazette', Rs. 16 including postage, in India. Rs. 19-8 including postage, abroad. Single copies Re. 1-8 each. Back numbers (if available) for the previous year Rs. 2-8 each, and all other back numbers Rs. 5 each.

Subscribers who so desire may have their copies packed flat in a strong envelope. The extra charge per annum is Re. 1-8 which should be added to the subscription. The envelopes are strongly made, and the *Gazette* is not folded, nor creased, in transit.

Papers and articles forwarded for publication are understood to be offered to *The Indian Medical Gazette* alone, and any breach of this rule will be followed by non-publication. When any such article appears in the *Indian Medical Gazette*, the copyright automatically becomes the joint property of the author or authors, and of the publishers.

The Editors of *The Indian Medical Gazette* cannot advise correspondents with regard to prescriptions, diagnosis, etc., nor can they recommend individual practitioners by name, as any such action would constitute a breach of professional etiquette.

A. K. SEN

(From the School of Tropical Medicine, Calcutta)

MUSTARD oil or certain adulterants in mustard oil have been implicated in outbreaks of epidemic dropsy by several workers. The so-called mustard-oil theory of epidemic dropsy is one of the earliest theories advanced to explain the cause of the disease and its prevalence in certain areas where mustard oil is extensively used for cooking purposes. The outbreaks in such areas are restricted to people who use mustard oil. Their neighbours who do not use mustard oil generally escape from this disease.

Sarkar (1926) recorded the production of symptoms resembling epidemic dropsy in man after the consumption of oil which had been accidentally adulterated with argemone oil (local name 'sialkata' or 'katakarak' oil) and Kamath (1928) described an outbreak of epidemic dropsy in Ganjam district amongst people who do not use mustard oil and, in this outbreak, oil pressed from certain seeds, locally known as *odissimari* seeds, was implicated as an adulterant. These and similar reports did not receive the attention they deserved till the mustard oil theory was again revived by the recent experiments of Lal *et al.* (1937) in which symptoms resembling epidemic dropsy were produced in human volunteers who ate food cooked in certain samples of mustard oil which had been implicated in outbreaks of epidemic dropsy. A control series whose food was cooked in pure mustard oil remained healthy. Although these workers showed that certain samples of mustard oil when used for cooking food produced symptoms of epidemic dropsy, the nature of the substance responsible for the production of symptoms in the implicated oil was not determined. The subject was reinvestigated and a careful study of the literature generally and of the work done by Lal and his co-workers, particularly on the aetiology of epidemic dropsy, suggested further work on the part played by argemone oil in the production of this syndrome. A test for this oil was found in Stewart and Boyd's (1928) book of public health laboratory

practice. This test consists in the addition of concentrated nitric acid to the sample of oil in a test tube. The tube is shaken and a positive reaction for argemone oil is shown by the development of an orange-yellow to a deep orange-red colour in the nitric acid layer. This test is also given by Lewkowitsh and Warburton (1922).

Positive reactions for argemone oil were obtained in the majority of the samples of oils collected from houses where there had been outbreaks of epidemic dropsy. Samples of *odissimari* seeds were obtained and identified by Mr. R. L. Badhwar to be the seeds of *Argemone mexicana* from which argemone oil is expressed. In view of these findings, that mustard oils implicated in natural outbreaks of the disease gave well-marked positive reaction for argemone oil and that Kamath's oil from *odissimari* seeds was argemone oil, it was arranged to give food cooked in these oils to certain volunteers. In one group of five individuals the food was cooked in pure mustard oil (expressed in the laboratory) to which was added known quantities of argemone oil (also expressed in the laboratory) from the seeds of *Argemone mexicana*. Another group of four individuals had their food cooked in samples of mustard oil implicated in natural outbreaks of the disease and which gave a positive reaction for argemone oil. A third group of individuals received a similar diet cooked in mustard oil which did not give a reaction for argemone oil. This last group showed no ill effects. The results obtained in the other two groups are summarized in tables A and B.

In one subject in each group there was transitory diarrhoea. In the group in which oil containing argemone oil was used for cooking, granular or hyaline casts were found in the urine of three of the five individuals but without any demonstrable albumin. In this connection it may be noted that granular casts were found in the urine of 7 of 16 individuals suffering from the naturally acquired disease.

Two individuals, one in each group, complained of dimness of vision but when examined showed no evidence of glaucoma.

Two of the four individuals whose food was cooked in incriminated oil developed cedema of the legs. In one the use of incriminated oil was stopped owing to intercurrent fever. In the fourth subject, although the incriminated oil was used for 21 days, there were no ill effects. This individual was the only non-Bengalee of the series and ate a limited amount of rice, eating instead bread (in the form of *chapaties*).

All the five individuals whose food was cooked in mustard oil containing known quantities of argemone oil developed well-marked cedema. Two of them (A 3 and A 4) in addition showed well-marked flush and cardiac symptoms (dilatation and murmur).

Food cooked in oil containing 5 per cent argemone oil was apparently relished by all, but the food cooked in 10 per cent argemone oil soon led to loss of appetite.

TABLE A

The results of taking food cooked in mustard oil containing known quantities of argemone oil. The argemone oil was expressed from Argemone mexicana seeds and mixed in proportion of 2 to 10 per cent with pure mustard oil (expressed from mustard seeds). Two ounces of this oil was used for cooking the daily food of each individual

*The use of 'incriminated' oil in this patient was stopped early owing to the development of intercurrent fever.

† Although this individual took the full amount of incriminated oil no symptoms developed. The diet of this subject (a non-Bengalee) differed from the diet of all others in that the intake of rice was limited and he took bread (as *chapaties*) once a day.

It appears that the principle or principles present in argemone oil have a cumulative effect, and, provided sufficient quantity of the oil is consumed, symptoms appear after an interval, even though the consumption of argemone oil or incriminated oil is stopped (see A 5). The oil used at the time of an outbreak can be pure and innocuous but it is the oil used some days before the onset of symptoms which is responsible.

Argemone oil is definitely more toxic to laboratory animals than mustard oil and various other bland oils. When argemone oil is heated to a stage when it 'fumes' well (at 240°C. for about 15 minutes) the oil (although it still gives a positive nitric acid test) is not toxic to animals. The toxic constituents are either destroyed or evaporated at this temperature. Heating at 100°C. or 150°C. has no appreciable effect in its toxicity to animals. Experiments are in progress to determine whether the toxic substance is present in the distillate or is destroyed at a temperature of 240°C.

The outstanding facts established by these experiments are—

1. Argemone oil when present in oil used for cooking gives rise to certain symptoms. The most marked effect is oedema of the legs and in some the development of a generalized flush and cardiac involvement. Similar symptoms are produced by the use of mustard oil implicated in outbreaks of epidemic dropsy and which gives a positive reaction for argemone oil.

2. Whether the condition produced is identical or not with the naturally-occurring epidemic dropsy cannot be definitely said at present, but there is no doubt that the use of oil containing argemone oil is harmful to man. There appears to be little doubt that consumption of adulterated oil produces symptoms which cannot be distinguished from those encountered in the naturally-occurring disease.

3. From the evidence available it appears that the adulteration of mustard oil with argemone oil may or may not be intentional on the part of those who grow the mustard plant, or of those who express or sell the oil. The plant *Argemone mexicana* is widespread, its seeds bear a superficial resemblance to mustard seeds and may be harvested along with them. It is possible that, because oil can be obtained from the seeds of this plant, efforts are not made to exclude these seeds in the harvesting of mustard seeds.

4. An oil containing argemone oil can be rendered harmless provided the oil is heated well. This is based on animal experiment and awaits confirmation by careful observations in man.

5. The plant *Argemone mexicana*, because of the ill effects produced in man by the oil expressed from it, must be considered as one of the poisonous plants of India. This plant is found widespread in mustard fields.

ERADICATION OF *HYMENOLEPIS NANA* INFECTION

By P. A. MAPLESTONE, D.S.O., D.Sc., M.B., B.S., D.T.M.
and

A. K. MUKERJI, M.B.

(From the Helminthological Research Department,
School of Tropical Medicine, Calcutta)

INFECTION with the dwarf tapeworm (*Hymenolepis nana*) is cosmopolitan and by no means uncommon, particularly in tropical and sub-tropical countries, but it rarely gives rise to symptoms which possibly accounts for the fact that efficient treatment of this condition never appears to have attracted a great deal of attention.

Consultation of the standard books on tropical medicine and parasitology reveals the fact that most of the usual anthelmintics (flox mas in some form or other, oil of chenopodium, thymol, hexylresorcinol and carbon tetrachloride) are all casually referred to by one or other author as being effective, but no detail is given. One of the most remarkable things about this subject is that in the sections devoted to treatment no book comments on the peculiar life history of this worm, and it is tacitly assumed that if a single dose of the chosen anthelmintic is given and no worms or eggs are found in the stool a day or two later the case is cured.

The main point of importance in the life history of this worm is that it does not need an intermediate host, and that once infection is acquired the eggs hatch in the intestine and the embryos enter the submucous coat of the intestinal villi where they grow and emerge into the lumen of the gut, reach maturity, deposit more eggs some of which hatch in the gut, and the cycle continues indefinitely. Also, on account of this characteristic of auto-infection, a single egg ingested in the beginning may eventually

(Continued from previous column)

Summary

It has been shown by feeding experiments in man that the oil expressed from the seeds of *Argemone mexicana* can produce signs and symptoms of epidemic dropsy.

give rise to a heavy and ever-increasing infection as generation succeeds generation. The time this cycle takes to be completed is of importance with regard to treatment, because an anthelmintic that will act on the worms in the intestinal canal, where it reaches the adult worms in relatively high concentration, is not likely to have much effect on the developing cysticercoids in the submucous layers of the villi as the objective in treatment with the toxic anthelmintics enumerated above is to get rid of them as rapidly as possible by evacuation of the bowels before they have time to be absorbed in any considerable amount.

A great deal of work has been done and much controversy has taken place on the identity of *H. fraterna* of mice and *H. nana* of man. Without entering into this controversy it may be stated, for the purpose of this paper, we consider it probable that *H. nana* in man and a fully adapted strain of the morphologically identical worm in mice have very nearly the same life history regarding the time of development of the various stages, length of life of the adults, etc. Shorh (1933) working with mice found that the length of life of adult worms does not exceed 25 days, and Hunninen (1935) observed, in a series of 36 mice, that one first showed eggs on the fourteenth day after swallowing eggs, 34 between the fifteenth and nineteenth days, and one on the twenty-fifth day. The latter worker also found that the cysticercoids began to return to the intestine from the villi 102 hours after entering them and that all had regained the gut by 144 hours (six days). He also noted that daily examination often fails to reveal eggs for periods of three or four consecutive days during the course of an infection; this is explained by one generation of adults having all died before the members of the next generation have reached sufficient maturity to begin depositing eggs.

If these accurately determined figures are applied to the problem of the treatment of *H. nana* infection in man three periods are found which must be taken into consideration in deciding if any course of treatment has been effective and a cure established: (1) Treatment must be continued for at least six days, (2) a negative period of at least five days is necessary before it can be said an infection has been eradicated, and (3) at least twenty-five days must elapse after cessation of treatment before a cure can be definitely claimed.

It is not possible to give any of the above drugs with safety over a period of several days, therefore none can be regarded as suitable for the treatment of *H. nana* infection. Kutschinsky (1933) apparently appreciated this fact for he records treating five cases with osarsol (stovarsol) tablets (dose not given) twice daily for three days. The summary of this paper in the *Tropical Diseases Bulletin* from which this information was obtained is very brief and it is said that in two cases there was temporary absence of eggs for about four months, and in

the other three complete disappearance of eggs. In the light of the above observations noted on mice, four months seems an unduly long time for an infection to remain latent and suggests that the method of egg demonstration used was not very effective so that if the infections were reduced in severity but not cured the eggs were missed until they had again become numerous. This idea is to some extent borne out by our experience recorded below in which stovarsol was found to be ineffective.

A female child, aged 2½ years, was admitted to hospital with 'debility' but no special symptoms. Eggs of *H. nana* were found in the stool at the routine stool examination and she was given stovarsol 1 grain three times a day for three days without apparent effect on the parasites. Six days later a dose of 1.5 c.cm. of filmaron oil (a proprietary preparation containing filicin combined with castor oil) was given and the stool was negative for *H. nana* the following day. The child was discharged and no more is known of it but it can be stated that the worms were resistant to stovarsol for three days and disappeared after a single dose of a male fern preparation. Whether it was cured or not is of course unknown.

A second child aged 10 years was given 2 grains of stovarsol three times a day for three days and continued to pass *H. nana* eggs daily for a week afterwards. The course of stovarsol was repeated and the infection was still present three days later.

These complete failures of stovarsol led us to consider that Kutschinsky's claims were not correct and that it was not worth while continuing with this form of treatment.

The somewhat similar life history of *Strongyloides stercoralis* and *H. nana*, as far as auto-infection of the host is concerned, suggested trying gentian violet because de Langen (1928) and Faust (Editorial, 1930) have shown, and we have confirmed their work in several unpublished cases, that gentian violet is successful in eradicating strongyloides.

Beginning on the fourth day after cessation of treatment the second child, noted above, who still harboured *H. nana* after two courses of stovarsol, each for three days, was given three half-grain doses of gentian violet a day for three days. The stool became free from *H. nana* eggs the day after treatment stopped and was free for the two succeeding days. This case was not observed further.

The rapid effect of gentian violet in this case indicated that it was worth further trial, and the protocols given below are a complete record of our results to date.

To avoid repetition, it may be stated that the gentian violet was given always in hard gelatin capsules, and the absence of *H. nana* eggs from the stools was determined by direct centrifugal flotation. All the patients were treated as inpatients.

Case 1.—Male, *æ*t. 30. Admitted into hospital for diabetes.

Ascaris, trichuris and *H. nana* infections found at the routine stool examination.

Given 16 grains of hexylresorcinol in capsules and all three infections persisted.

Given gentian violet 1 grain, *t.i.d.*, for five days. *H. nana* eggs disappeared the day after treatment stopped and were still absent eight days later. No further observation.

Case 2.—Male, *æ*t. 26. Admitted with pellagra.

Hookworm, ascaris and *H. nana* eggs and strongyloides larvæ found at the routine stool examination.

Given oil of chenopodium 1 c.cm. and tetrachlorethylene 4 c.cm.

Next day gentian violet 1 grain a day, *t.i.d.*, for six days begun.

Two days after cessation of treatment a few hookworm eggs only were found and a stool culture put up on the same day exhibited hookworm larvæ only, when extracted a week later.

The oil of chenopodium may have played some part in causing the disappearance of the *H. nana* infection. The time of observation was much too short to say if the case was cured.

Case 3.—Male, *æ.t.* 5. Admitted for 'diarrhœa'.

Ascaris eggs found at routine stool examination.

Given two treatments ten days apart, each of santonin $\frac{1}{2}$ grain and oil of chenopodium 5 minims.

Examination after second treatment showed ascaris infection to be cured but *H. nana* eggs were found for the first time in the final examination. This was a light infection.

Gentian violet $\frac{1}{2}$ grain twice daily for six days was ordered.

Vomiting troublesome so gentian violet discontinued after one day's treatment.

Gentian violet resumed after two days and vomiting recurred so further treatment was abandoned.

Four days after treatment was stopped no *H. nana* eggs could be found in the stools.

This case was not observed longer and as the stools were negative for *H. nana* eggs at several examinations prior to treatment evidence of the value of gentian violet in this case is not conclusive.

Case 4.—Male, *æ.t.* 32. Admitted for 'diarrhœa'.

H. nana infection found at routine stool examination.

Gentian violet 1 grain, *t.i.d.*, for six days ordered.

Complained of nausea so treatment stopped after four days.

No *H. nana* eggs in stool for three days after cessation of treatment.

Case 5.—Male, *æ.t.* 8. Admitted for oriental sore.

H. nana infection found at routine stool examination.

10th January. Gentian violet $\frac{1}{2}$ grain, *t.i.d.*, for seven days given.

12th January to 4th February (24 days). No *H. nana* eggs found and examination discontinued, and the case was considered cured.

As patient was still in hospital his stool was again examined on 8th March and found positive.

Gentian violet $\frac{1}{2}$ grain, *t.i.d.*, for seven days was repeated.

Stool negative from end of treatment for seven days, when eggs reappeared.

No more treatment was given for about a month.

7th May. Gentian violet $\frac{1}{2}$ grain a day, *t.i.d.*, for three days.

Stool negative for three days only.

14th May. Gentian violet $\frac{1}{2}$ grain, *t.i.d.*, for three days.

16th and 17th May. No *H. nana* eggs in stool.

18th May. Eggs again present.

Discharged from hospital and treated as an outpatient.

21st May. Gentian violet $\frac{1}{2}$ grain a day, *t.i.d.*, for three days.

3rd June. One egg found.

18th July. No eggs found.

20th August. No eggs found.

This case is the most instructive of the series as it indicates that a period of 24 days in which *H. nana* eggs cannot be found is not sufficient for establishment of cure. As examination was not carried out between the 25th and 56th days after becoming negative it is not possible to say the exact day on which infection again became manifest.

Another point of interest is that a period of three days' treatment appears to be as effective as one of seven days.

Case 6.—Male, *æ.t.* 13. Admitted with malaria.

Hookworm and strongyloides infection found at routine stool examination.

Treated with tetrachlorethylene and cured of hookworm infection.

Gentian violet $\frac{1}{2}$ grain a day, *t.i.d.*, for seven days.

Post-treatment stool examination showed *H. nana* eggs present.

Strongyloides disappeared from the stool after the third day of treatment and was never found again, even on culture of stool at the end of the period of observation two months later.

Eggs of *H. nana* disappeared after 4th day of treatment and reappeared again 17 days later.

Gentian violet $\frac{1}{2}$ grain, *t.i.d.*, for seven days repeated.

Eggs not present from 4th day of treatment until seven days after treatment stopped (11 days negative). Patient discharged.

A stool brought 18 days after discharge was positive.

Further treatment was refused.

Case 7.—Female, *æ.t.* 37. Admitted with *T. saginata* infection and *H. nana* found at once.

Gentian violet 1 grain, *t.i.d.*, was ordered but as the woman had a considerable amount of nausea and vomiting the usual course was modified as follows:—

First day. One dose only, on account of nausea.

Second day. Three doses, vomited third dose.

Third day. Three doses, nausea and vomited once.

Fourth day. Three doses given concurrently with 15 grains of bismuth carbonate and vomited in the night.

Fifth day. Vomiting continued so treatment stopped.

The *T. saginata*, snapped approximately two inches from the head, was passed two days after treatment stopped. Four days after cessation of treatment with gentian violet a dose of 4 c.cm. of tetrachlorethylene was given but no worm was found.

Signs of *H. nana* infection disappeared on the last day of treatment and the stool remained free from eggs until the woman was discharged from hospital—negative period 23 days.

This woman was treated with carbarsone for 10 days for chronic amœbiasis, beginning one week after cessation of gentian violet.

Gentian violet was given before tetrachlorethylene to see if it had any action on *T. saginata* as well as on *H. nana*. Although it failed to eradicate the large tapeworm the drug appears to have some effect on it because just after treatment stopped the major portion of the worm was spontaneously evacuated and it was found that in the gravid segments the uterus was deeply stained, although the remainder of the tissue was the usual dull-white colour. Higher up in the chain the sexually-mature segments did not appear stained at all.

Case 8.—Male, *æ.t.* 30. Admitted for filariasis with febrile attacks.

H. nana discovered at routine stool examination.

26th April. Gentian violet 1 grain, *t.i.d.*, for three days ordered.

27th April. Three doses given but nausea and vomiting later in evening.

28th April. Gentian violet omitted. *H. nana* eggs still present.

29th April. Three doses given and retained, some nausea. Stool negative.

30th April. Three doses given and retained, some nausea. Stool negative.

1st May. Vomiting began after second dose so no more given.

3rd May to 30th May. Stool examined daily, no eggs seen.

2nd June. One *H. nana* egg seen.

3rd June to 2nd July. No eggs seen; discharged.

Case 9.—Male, *æt.* 42. Admitted for diabetes.

H. nana eggs found at routine stool examination.

Three courses of gentian violet were given, each consisted of 1 grain, *t.i.d.*, for three days with intervals of four days between them. There was no apparent effect on the infection which persisted throughout, and there was no nausea and vomiting so all the drug was retained. This seems to be an unusually resistant case.

Case 10.—Male, *æt.* 4. Admitted with 'dysentery' not confirmed by bacteriological or protozoological examination, and there is no evidence the symptoms were caused by *H. nana* because they cleared up before treatment was commenced.

H. nana and trichuris eggs found at routine stool examination.

7th to 9th September. Gentian violet $\frac{1}{2}$ grain, *t.i.d.*

12th September. No *H. nana* eggs seen.

14th to 16th September. Gentian violet $\frac{1}{2}$ grain, *t.i.d.*

17th to 21st September. No eggs seen.

21st to 23rd September. Gentian violet $\frac{1}{2}$ grain, *t.i.d.*

22nd September. *H. nana* eggs again present.

No more eggs were seen up to the 1st October when patient was discharged. There was no vomiting throughout the treatment.

It will be seen that this case became negative after the first course of treatment, but it was decided to give two more courses of the same duration as in case 9. On the second day of the third course eggs again appeared which indicates the advisability of giving more than one three-day course even if the stool is negative after the first course.

Case 11.—Male, *æt.* 4. Admitted with 'dysentery' not confirmed by bacteriological or protozoological examination, and not caused by *H. nana* infection which was found at routine stool examination.

22nd to 24th December. Gentian violet $\frac{1}{2}$ grain, *t.i.d.*

26th December to 4th January. No *H. nana* eggs seen.

5th January. Eggs and segments of *H. nana* found.

6th to 8th January. Gentian violet repeated.

9th to 19th January. No eggs seen.

20th January. Eggs again present.

21st to 23rd January. Gentian violet repeated.

Remained positive until discharged on 26th January.

This child never vomited so all the gentian violet given, was retained. The treatment varied slightly from that in case 10 because the second and third treatments were withheld until eggs appeared in the stools. This patient is still under observation.

Case 12.—Male, *æt.* 22. Admitted with *H. nana* infection but no symptoms. Gentian violet 1 grain, *t.i.d.*, for three days. No nausea or vomiting. Stool became negative three days after cessation of treatment and remained negative for three more days, after which the patient had to leave hospital. A stool brought for examination 17 days later contained *H. nana* eggs. This case is still under observation.

Conclusion.—These observations indicate that gentian violet is a valuable drug for treatment of *H. nana* infection, possibly the only one of any real value. Much more work is needed to decide whether a course of treatment for a week or longer or several courses of three days'

THE COMPARATIVE VALUE OF OIL OF CHENOPodium AND TETRACHLOROETHYLENE AS ANTHELMINTICS FOR USE IN MASS TREATMENT

By K. P. HARE, M.B., B.S. (Lond.), L.M.S.S.A.

Medical Officer, Tingri Medical Association

and

S. C. DUTTA, L.M.P.

Assistant Medical Officer, Itakhooli Tea Estate

Introduction

THE problem of hookworm infection bears several aspects of interest to the tea estate medical officer. From the clinical point of view of the practising physician, severe ankylostomiasis, though not an everyday occurrence, is a potent source of serious and, sometimes, fatal illness. 'Water-sore' or ground-itch, though not serious, is a very common disability which occurs during the summer months when the labour force is required to be at the peak of efficiency and when the physician is already busy dealing with the seasonal influx of cases of malaria and pneumonia. From the public health point of view of the medical officer, as

(Continued from previous column)

duration at weekly intervals will prove to be the best. The interrupted form of treatment instead of a continuous course of six or seven days was tried on some of our cases in an effort to avoid the nausea and vomiting which is fairly common with this drug.

As far as our work goes the case records indicate that the minimum period of observation for a stool to be continuously negative is over 24 days, and hence is probably not far from the estimate based on the work of Shorb and Hunninen, quoted above. It is suggested that until further information on the subject is available this period should be placed at one month at least, but even a longer time than this is preferable until exact figures are obtained.

The results recorded are admittedly incomplete, and they are published with the hope that other workers, who have the opportunity, may be induced to follow the work up on the lines indicated in this paper.

administrator, hookworm infection bears the cardinal stamp of interest in that it is eminently preventable by the provision of effective sanitation which prevents contamination of the soil and therefore removes the infective larvæ out of reach of the coolies' feet.

Unfortunately, very few tea estates have yet been provided with any system of sanitation at all so that the only way of breaking the circle of infection is by rendering worm-free the infected members of the population. Now, from this point of view, one hundred persons each harbouring one worm are of far more serious import than one person harbouring a hundred worms; for the area of scatter of infection is so much greater. In the tea districts of Assam, probably ninety per cent of the adult population harbour hookworms though the large majority of infections are very light so that, effectively to break the infectivity circle on its human side, virtually mass anthelmintic treatment is required.

The choice of anthelmintic is, therefore, a matter of some importance. For use in mass treatment, an anthelmintic must be:—

- (1) Non-toxic.
- (2) Reasonably palatable.
- (3) Easily dispensed.
- (4) Effective in one dose.
- (5) Inexpensive.

The fourth requirement is important as every treatment given means the loss to the estate of one day of labour, a vital consideration when production costs must be kept down to the minimum. Most authorities, *e.g.*, Chopra (1936), assess the value of an anthelmintic by comparing the proportion expelled of the estimated total worm load with the results obtained from some standard anthelmintic. We feel that this method is unsatisfactory. Since it must be based on experiments on heavily infected cases the results do not necessarily apply to the cases of light infection whose importance we have stressed. The heavily infected cases can always be dealt with individually since they are few in number. We consider that when assessing the value of a drug for mass treatment purposes, the only effective method is the determination of the percentage of infected persons, taken at random, who are rendered worm-free by one dose of the drug under test. Since it may be taken as accepted that the Clayton-Lane method of direct centrifugal flotation is the most accurate means of diagnosing hookworm infection, we feel that to find a stool egg-free when subjected to this test may be regarded as proof that the person who passed it is worm-free, provided a sufficient interval has elapsed since the exhibition of the anthelmintic.

The drugs in general use for expulsion of hookworms are carbon tetrachloride, oil of chenopodium, and tetrachlorethylene. Carbon tetrachloride is far from being non-toxic and several fatalities have been reported following

its use even when reasonable precautions have been taken. It is not, in our opinion, a suitable drug for mass treatment. Oil of chenopodium is probably, at present, the most largely used anthelmintic, but it is costly and is very unpleasant to take. There is a large literature in existence testifying to its efficacy and it is discussed in detail in all the standard textbooks of tropical medicine. Tetrachlorethylene, though it has been in use for at least ten years, has not amassed a considerable literature and a perusal of several standard textbooks provided only a limited amount of information. Manson-Bahr (1935) does not mention it at all, nor does Majumdar (1938). Banerjee and Bhattacharya (1938) mention it as 'a most effective anthelmintic against hookworm' and quote Maplestone for mode of administration. Chopra (1936), however, fully discusses its chemical constitution, pharmacological action and toxicity, and gives references to six papers on the subject. He comes to the conclusion that 'the cure rate with tetrachlorethylene is probably slightly greater than with (carbon) tetrachloride' and that 'tetrachlorethylene would be a very safe drug to employ as an anthelmintic'.

Manson (1934) carried out an extensive comparison between tetrachlorethylene alone, oil of chenopodium alone and a combination of the two and concluded that, within the scope of his investigation (which did not include examination by 'DCF') 'tetrachlorethylene is a safe and reliable anthelmintic for general use' and that 'tetrachlorethylene in a dose of 4 c.cm. and mixed treatment . . . proved to be definitely the best methods of treatment for mixed helminth infections and for hookworm infections'.

Maplestone and Mukerji (1937) have recently published a further series of cases confirming their previously recorded favourable impressions of tetrachlorethylene. They used the DCF method so that their figures are more comparable with ours. What information is available indicates that tetrachlorethylene is reasonably non-toxic and is effective. It is certainly more palatable than oil of chenopodium, is not more difficult to dispense, and its cost per dose is definitely less. The present investigation is an attempt to compare the efficacy of single doses of oil of chenopodium and of tetrachlorethylene in order to satisfy our fourth requirement, namely, efficacy in one dose.

Material and technique

The experimental subjects were 188 consecutive coolie patients admitted for hookworm treatment to estate hospitals under the senior author's charge. They had been picked out at labour force musters as being anæmic, or lethargic, or badly nourished, and in every case the existence of hookworm infection was confirmed microscopically by the senior author, personally, before treatment was given. Alternate batches of a dozen or so were treated with

the two drugs. Seventeen cases were given twenty minims of oil of chenopodium. Eighty-four cases had thirty minims of oil of chenopodium and eighty-seven cases had four cubic centimetres of tetrachlorethylene. Of these, ninety-four chenopodium cases (94 per cent) and forty-six tetrachlorethylene cases (52 per cent) were treated personally by the junior author. The remainder were treated substantially according to the same technique which was as follows:—

All the patients were treated as in-patients in order to allow of close observation and in every case the medicine concerned was poured directly into the mouth and the patient instructed to open the mouth afterwards to ensure that the whole dose had been swallowed. In any case where the medicine was vomited, the dose was repeated after a few minutes. The doses were administered in the early morning on an empty stomach and no food was given until noon when milk and sago were allowed. The oil of chenopodium used was guaranteed to be of B.P. strength and the tetrachlorethylene was obtained from a reliable source. The total dose of oil of chenopodium was split up into separate portions of ten minims each shaken up in one ounce of fifty per cent magnesium sulphate solution and the separate doses were administered at intervals of one hour. The total dose of tetrachlorethylene was given at one time shaken up with two ounces of a saturated solution of sodium sulphate. On the fourteenth day after administration of the anthelmintic a second stool was obtained from each case and subjected to Clayton-Lane's method of direct centrifugal flotation (DCF) by the senior author personally. The results were assessed as follows:—

No eggs in whole area of cover-slip = absolute cure.

One, two or three eggs in whole area of cover-slip = partial cure.

Four to twenty eggs in whole area of cover-slip = improvement.

More than twenty eggs was classified as 'no cure'.

Though, for the reasons stated above, we only attach importance to absolute cures we have included the other assessments in order to simplify comparison of our results with those of other workers.

TABLE

OIL OF CHENOPODIUM (TWENTY MINIMS)

17 cases

Degree of cure			Number	Percentage
Absolute cure	Nil	..
Partial cure	1	5.9
Improved	Nil	..
Not cured	16	94.1

OIL OF CHENOPODIUM (THIRTY MINIMS)

84 cases

Degree of cure			Number	Percentage
Absolute cure	4	4.8
Partial cure	7	8.3
Improved	19	22.6
Not cured	54	64.3

TETRACHLORETHYLENE (FOUR CUBIC CENTIMETRES)

87 cases

Degree of cure			Number	Percentage
Absolute cure	42	48.3
Partial cure	23	26.4
Improved	9	10.4
Not cured	13	14.9

Table showing results of administration of single doses of anthelmintics.

Results

The results of the investigation are shown in the accompanying table where we state the number of cases treated with each preparation, the number found in each class of 'cure' at the second examination and the same numbers expressed as percentages of those treated. It is obvious from this table that for efficiency in a single dose, tetrachlorethylene is infinitely superior to oil of chenopodium and, other things being equal, is the drug of choice for use in mass hookworm treatment. Our results with oil of chenopodium are, frankly, disappointing and are much inferior to those of other workers. Our standard of cure may have been more severe but another fact of possible importance is that some certainly, and possibly many, of these coolies have been previously treated with oil of chenopodium and it may be that a condition of 'chenopodium-resistance' can occur. We have never heard of such a condition being described but it seems an interesting possibility.

With regard to toxicity, all the patients treated with tetrachlorethylene experienced a sensation of drunkenness (which they rather enjoyed) lasting an hour or so. One case, a debilitated female of eighteen, suffered from severe vomiting, giddiness and marked drowsiness. After cold had been applied to the head she recovered and was perfectly well by the evening. Her cardiac condition was normal.

The coolies were emphatic in their opinion of the palatability of tetrachlorethylene as compared with oil of chenopodium. They considered it to have a sweet taste and a pleasant odour and pointed out that it did not cause any burning sensation in the mouth. These points all contrasted strongly with oil of chenopodium which is, by no means, one of their favourite drugs.

Tetrachlorethylene is simple to dispense using the method of administration described and has the added attraction to the compounder that he need only dispense one dose as against several.

Tetrachlorethylene is extremely cheap in use. One pound, costing Re. 1-14-0, represents twelve fluid ounces or approximately 360 c.cm. corresponding to ninety doses. The cost per dose is, therefore, one-third of an anna. One pound of oil of chenopodium, costing Rs. 13, represents nineteen fluid ounces, or 304 doses, the cost per dose being two-thirds of an anna—exactly double the cost of tetrachlorethylene.

Conclusion and Summary

(1) Attention is drawn to the importance in prophylaxis, as distinct from treatment, of mass anthelmintic treatment directed against the hookworms, and the properties of the ideal anthelmintic are stated.

(2) The assessment of the comparative value of anthelmintics is discussed and reasons given for preferring an assessment based on percentage of persons cured rather than percentage of worms expelled.

(3) Carbon tetrachloride, oil of chenopodium and tetrachlorethylene are discussed from the point of view of their literature.

(4) An experimental investigation into the efficacy of single doses of oil of chenopodium and tetrachlorethylene, checked by examination of the stools by Clayton-Lane's DCF method fourteen days after exhibition of the anthelmintic, is described and the results tabulated.

(5) It is concluded that tetrachlorethylene is a superior drug for mass treatment to oil of chenopodium as it more nearly fulfils all the five requirements of the ideal anthelmintic.

Acknowledgments

We wish to record our appreciation of the kindness of Mr. F. O'Connor, Manager, Itakhooli T. E., in allowing us to fill his hospital with our cases and his unfailing courtesies in allowing them leave from their garden duties.

We also wish to thank Dr. A. T. Ray, Assistant Medical Officer, Deohal T. E., who personally administered the majority of the doses not given by the junior author and who favoured us with a full report of his clinical impressions regarding the two drugs.

BREVET-COLONEL, I.M.S.

Honorary Physician to the King

and

B. M. DAS GUPTA

(From the School of Tropical Medicine, Calcutta)

In recent publications Chopra and Das Gupta (1938) and Das Gupta and Chopra (1938) have shown that certain sulphonamide compounds, namely soluseptasine and prontosil, have a definite action on *Plasmodium knowlesi* infection in *rhesus* monkeys, when administered in disproportionately large amounts as compared with human dosage. The reason for testing the activity of this new chemotherapeutic agent of the sulphonamide series on the same infection is to ascertain whether a relatively smaller dosage will prove effective in eradicating the infection. The daily dosage, as recommended for adults in various bacterial infections for which the drug is intended, is 4 to 8 tablets each containing 0.5 gramme of the compound. Considering the comparative weights of man and monkeys the dose for a monkey weighing 4 kilogrammes comes to 0.13 gramme. As previous experience has taught us that oral administration of drugs to monkeys is extremely difficult, we asked the manufacturers if they could make it suitable for parenteral administration. Accordingly they prepared an oily suspension of this compound, containing 0.5 gramme of the active ingredient in 2.5 c.cm.

Experiment 1.—Monkey (*Silenus rhesus*) weighing 4.184 kilogrammes was experimentally infected with *Plasmodium knowlesi*.

Date	Parasites per 1,000 leucocytes	Treatment	REMARKS
12-12-38	32,400	0.74 c.c. of the oily suspension = 0.15 gramme of the compound given intramuscularly.	
13-12-38	28,000	Do.	
14-12-38	4,200	Do.	
15-12-38	Very scanty.	Do.	Very scanty degenerating forms. Mono-nuclears with ingested hæmozoin pigment.
16-12-38	0	Do.	
17-12-38	0		

The blood was examined daily till the end of December 1938, thereafter once a week till the 24th February, 1939. No parasites have ever been found.

Experiment 2.—Silenus rhesus, 4.025 kilogrammes in weight. Experimentally infected with *P. knowlesi*.

Date	Parasites per 1,000 leucocytes	Treatment	REMARKS
16-1-39	1.600	0.5 c.c. of the suspension = 0.1 gramme intramuscularly.	
17-1-39	5.700	Do.	
18-1-39	Scanty	Do.	
19-1-39	0	Do.	Many pigment-bearing leucocytes.
20-1-39	Very scanty.	..	Very scanty parasites detected in thick films after prolonged search.
21-1-39	0		
22-1-39	0		

From 22nd January to 27th February thick films have been examined bi-weekly but the results were invariably negative.

Experiment 3.—Silenus rhesus, 4.420 kilogrammes in weight. Experimentally infected with *P. knowlesi*.

Date	Parasites per 1,000 leucocytes	Treatment	REMARKS
19-2-39	8.200	0.25 c.c. of the suspension = 0.05 gramme intramuscularly.	
20-2-39	16,800	Do.	
21-2-39	1,200	Do.	
22-2-39	Very scanty.	Do.	Very scanty parasites detected after long search in thick film.
23-2-39	0	Do.	
24-2-39	0	..	A few pigmented leucocytes.

Comments.—From the above experiments it is evident that, unlike prontosil and soluseptasine, this compound is capable of destroying the monkey plasmodium (*Plasmodium knowlesi*) in dosage which is even less than what is regarded as the proportionate dose for a monkey as compared with that of man. Moreover, the parasites once disappearing, after a 5-day course of treatment, do not appear again in the peripheral blood at least in sufficient numbers to be detected in thick films. This is different from what happens after treatment of *P. knowlesi* infection with atebirin. For it has been noted by the present observers (Chopra, Das Gupta and Sen, 1933) that although atebirin exerts a

CHEMOTHERAPY OF GONORRHOEA AND OTHER MINOR VENEREAL DISEASES WITH SULPHANILAMIDE COMPOUNDS—A CLINICAL STUDY

By R. V. RAJAM, M.B., M.S., M.R.C.P.
Venereal Specialist, General Hospital, Madras

P. N. RANGIAH, M.B., B.S.

Honorary Assistant Surgeon, Venereal Department,
General Hospital, Madras

and

Dr. (Mrs.) T. MASILAMANI, M.B., B.S., D.G.O.

Honorary Assistant Surgeon, Venereal Department,
General Hospital, Madras

It is fairly evident now from the numerous reports of investigators that the sulphanilamide compounds are a distinct and invaluable addition to our therapeutic armamentarium in the fight against coccal and bacterial infections. Following on its dramatic effect in meningococcal infection, it was but in the fitness of things that the drug should have been tried in the closely allied but much more widely prevalent gonococcal infection.

With the lead given by Dees and Colston (1937) in their preliminary report on 19 cases of gonorrhoea treated successfully with sulphanilamide, a number of clinicians, American and European, have given the drug a trial. From the many reports which have appeared and are still appearing, it seems fairly certain that we have in these compounds a potent chemotherapeutic agent in the treatment of gonococcal infection. But unfortunately the drug is definitely toxic and evidence is accumulating that serious and fatal results may follow the administration of the drug. The drug has been deemed to be a potential marrow poison with the ever imminent risk of inducing those often fatal blood dyscrasias, hæmolytic anæmia and granulocytopenia. Its very therapeutic potency

(Continued from previous column)

very powerful action on this infection, the parasites almost invariably reappeared in 10 to 15 days and multiplied with the same rapidity as in the primary attack, causing the death of the animal if prompt treatment was not accorded. In view of the encouraging results obtained with this drug in monkey malaria, it is well worth trying on human cases.

seems a disadvantage in that there is evidence that the drug is being indiscriminately administered or prescribed in all and sundry conditions from a common cold to epilepsy. In a disease like gonorrhoea, in which there is always a tendency on the part of the patient to avoid publicity and exposure, the comparative cheapness of this group of drugs under the cut-throat competition of rival manufacturing firms, the ease and the success of oral administration, and the absence of any restriction on their sale, afford ideal conditions for self-treatment with its very real dangers. The gonococcus being a purely human parasite does not lend itself to study in laboratory animals under controlled conditions. This is a great handicap in the experimental evaluation of the sulphanilamide group of drugs with reference to toxicity and therapeutic effectiveness. The exact mode of action of this drug is as yet undetermined. Bacteriologists are of opinion that the drug is but feebly bactericidal, and exerts its action by arresting the growth of bacteria (bacteriostatic). This bacteriostatic action of the drug may be of great clinical importance in two divergent ways :—

1. Under inadequate dosage and/or short duration of treatment, the drug may simply render the gonococci temporarily ineffective and avirulent, inducing a condition of precocious latency. Such latent carriers under a false sense of security will be a menace to the non-infected.

2. The organisms maimed and rendered effete by the drug may be completely destroyed in the body by the natural immunity mechanism. Thus, the chemotherapeutic action of the drug reinforced by the natural immunity reactions of the body explains the many permanent cures already reported in the literature.

The optimal dosage of the sulphanilamide compounds is still a matter of controversy. Long's biochemical studies, corroborated by those of Bannick and Low and others, seem to indicate that a concentration of 5 to 7 milligrammes of the drug in 100 c.cm. of blood is essential for therapeutic effectiveness. This concentration may be maintained by a daily dosage of 4 to 5 grammes with uniform spacing of the intervals between individual doses.

The clinical study attempted in this paper comprises mostly our observations on the chemotherapy of gonorrhoea. A certain number of other minor venereal diseases were also subjected to the treatment with sulphanilamide. All the cases of gonorrhoea that attended the venereal clinic, General Hospital, Madras, for the past nine months with few exceptions were treated with the new drug. Our cases include every type of gonorrhoea, acute, subacute, chronic, complicated, first attacks, and subsequent attacks. The majority of the patients were ambulatory.

Male cases

The diagnosis of gonorrhoea was based on a complete clinical and bacteriological examination. The nature of the discharge, the appearance of the urine by the glass test, the condition of the adnexal structures, and the presence or absence of complications were completely recorded before commencing treatment. The ambulatory patients were asked to report themselves daily during the period of treatment. Sulphanilamide or some other allied product was administered orally. The patients were given detailed instructions as follows :—

- (1) The tablets are to be taken with a glass of water after meals three or four times a day at regular stated intervals.
- (2) The patients are warned to avoid eggs, onions, garlic, saline purgatives, undue exposure to sunlight, and any form of strenuous exertion.

During the daily visits, every patient receiving sulphanilamide treatment was carefully gone through. Smears were taken for bacteriological examination, the urine was examined by the two-glass test, alleviation or disappearance of symptoms was recorded, and any toxic reaction noted.

In the majority of cases studied, the clinical response to sulphanilamide was dramatic. The urethral discharge ceased, and the urine became crystal clear with an occasional mucus shred, in 48 to 72 hours after commencing treatment. The symptoms of strangury, frequency and pain disappeared even quicker after the first day's treatment. There was a corresponding improvement in the bacteriological examination of smears and centrifuged deposit of the urine. By the end of the first week, the urethra was perfectly dry, the urine sparkling and clear, the smears showed only a few epithelial cells, an occasional pus cell in different stages of disintegration and the complete absence of gonococci. How futile, time consuming and nerve-racking, the older methods of treating gonorrhoea seem in contrast to sulphanilamide therapy. The doctor of 1950, by which time the chemotherapeutic treatment of gonorrhoea will have been standardized, will wonder at the ineptitude of his forbears with their multiple and uncertain methods of treatment, with weeks and months of irrigations, instillations, instrumentation, chemical dyes, and dubious vaccines.

The total number of cases of gonorrhoea treated in the department during a period of nine months was 737. Out of this number, only 439 cases are included for purposes of statistical analysis and evaluation in the present study. The remaining 298 cases defaulted after inadequate treatment, and hence are excluded from this survey.

The 439 cases consist of 343 cases of uncomplicated gonorrhoeal urethritis and 96 cases of gonorrhoea with complications.

Gonorrhœal urethritis (without complication)—
343 cases

Drugs used.—A number of drugs of the sulphanilamide group were under trial in the treatment of disease, as table I will show :—

daily dosage was tried to find the optimum dose compatible with the minimum of toxic reaction. An analysis of 96 cases of apparent cure treated with varying doses of sulphanilamide for about a week reveals the influence of daily dosage on the rapidity of response.

TABLE I

Drug administered	Number of cases treated	Number cured	Percentage cured	Number failed	Percentage of failures
1. Proseptasine (M. & B.)	25	4	16	21	84
2. Prontosil album (Bayer)	33	26	79	7	21
3. Uleron (Bayer)	10	7	70	3	30
4. Urea sulfazide (Union Drug)	20	8	40	12	60
5. Sulfanilamide (P. D. & Co.)	255	202	80	53	20
TOTAL	343	247	72	96	28

Though the results of the treatment of the infection with drugs 1, 2, 3 and 4 were based on a much smaller number of cases than with drug 5, we are of opinion that Sulfanilamide is much the most efficient, with Prontosil album running a close second. In our hands both Proseptasine and Urea Sulfazide have proved disappointing as may be gathered from the large percentage of failures in table I. As regards Uleron we have not been able to corroborate the claims put forward by German clinicians that it is therapeutically superior to sulphanilamide. The drug seems to be capricious in its action. In our limited experience with Uleron we found that bacteriological cure does not keep pace with the clinical cure and scattered gonococci, without pus cells and with staining abnormalities continue to be observed under the microscope even after apparent clinical cure.

Influence of daily and total dosage

A period of three weeks was fixed tentatively for the duration of sulphanilamide therapy and the drug was administered for three successive six-day periods with an interval of a day's rest between the courses. A number of scales of

TABLE II

27 cases received	22 per cent apparent cure in 3 days.
3 grammes daily	33 " " " " 5 "
with	45 " " " " 7 "
47 cases received	25 per cent apparent cure in 3 days.
4 grammes daily	50 " " " " 5 "
with	25 " " " " 7 "
22 cases received	68 per cent apparent cure in 3 days.
6 grammes daily	18 " " " " 5 "
with	14 " " " " 7 "

After the first week of treatment, a maintenance dosage of 2 to 3 grammes daily was administered in successful cases for the next two weeks.

The percentage of cures was studied with reference to the total dosage administered during the three-week period in 255 cases.

The results of statistical analysis of our cases seem to confirm the observations of other workers in the following points :—

- (1) An optimal daily dosage of 4 to 5 grammes of sulphanilamide during the first week of therapy is necessary for rapid clinical response.

TABLE III

	Failures	Percentage of failures	Cures	Percentage of cures
Total dosage below 40 grammes	49	26	141	74
Total dosage above 40 grammes	4	6	61	94

TABLE IV

Duration of disease	Number of successful cures	Percentage of cures	Number of failures	Percentage of failures
Under one week	30	59	21	41
One to four weeks	61	77	18	23
Beyond four weeks	54	93	4	7

- (2) A total dosage of 50 to 60 grammes of the drug, spread over a period of three weeks, gives the highest percentage of permanent cure of cases.
- (3) If a case of gonorrhœal urethritis does not respond by the end of the first week of massive therapy, it is futile to continue the administration of the drug during the subsequent weeks.
- (4) To avoid relapses and resistance the chemotherapy should be uninterrupted during the first week.
- (5) Smaller daily doses of 1 or 2 grammes, far from being beneficial, seem to make the infection more resistant and liable to induce complications like epididymitis and arthritis.

The rate of cure of gonorrhœal urethritis with reference to the duration of the disease was investigated in 188 cases and is shown in table IV.

The results of chemotherapy of gonorrhœal urethritis of less than a week's duration appear distinctly disappointing and lend support to the view, put forward by Cokkinis and his co-workers, that in cases of gonorrhœa of less than one week's duration, sufficient time has not elapsed for the body to develop the immunity mechanism to deal with the gonococci arrested by chemotherapy. Further, it is our impression that premature chemotherapy renders the infection more resistant and delays the development of the natural immunity mechanism. The marked improvement in the results of cases of one to four weeks and beyond four weeks' duration is evidence of the time taken by the body to develop its own resistance and to utilize effectively the drug circulating in the blood for the cure of the infection. In our study of cases of gonorrhœal urethritis of more than four weeks we have found that a less total dosage of the drug and a shorter period of treatment (two weeks) suffice to bring about cures in most of the cases. With the same object of assessing the value of chemotherapy in the first and subsequent attacks of gonorrhœa, 120 cases were studied of which 66 were first attacks and 54 were second, third and subsequent attacks. 79 per cent of the former and 93 per cent of the latter were recorded as cured.

Complications of gonorrhœa in the male— 96 cases

Table V gives the list of complications.

Gonorrhœal epididymitis—31 cases

TABLE VI

Number of cases treated	Drugs employed	Results regarding epididymitis and urethral infection
20	Sulfanilamide	All the cases cured—both epididymitis and urethral infection.
4	Urea sulfazide	Three cases responded well to epididymitis—one case no response to epididymitis and urethral infection.
3	Proseptasine	All failed.
2	Prontosil album	Both the cases cured.
2	Uleron	One was a failure; the other was cured.

The response of epididymitis to treatment with sulphanilamide or its product was eminently satisfactory. The pain disappeared dramatically within 24 hours and the swelling completely subsided by the end of the week without even leaving a residual nodule at the lower pole of the organ, a common feature with the older methods of treatment. The associated urethral infection also was cured in the majority of the cases. No other local adjuvant treatment was applied to the scrotum except a mechanical support.

Joint affections

Thirty-one cases were treated of which 24 were admitted as in-patients. The results of treatment with sulphanilamide compounds of gonorrhœal joint affections were not as satisfactory as was expected. Though the response of the associated urethral infection was as good as in the other uncomplicated cases of gonorrhœa, the improvement of the joint condition was slow and erratic. The pain, swelling and limitation of movement subsided only slowly leaving at the end of a complete course of therapy, a degree of residual disability of pain and swelling, etc., which was annoying to the patient and disappointing to the doctor. Another distressing thing we noticed in the treatment of joints with sulphanilamide is that during the therapy, while the originally affected joint or joints were showing signs of improvement, other joints became consecutively or successively involved, a sort of Herxheimer reaction, which in their turn showed signs of abatement. This slow improvement in the condition of the joint with sulphanilamide prompted us to try a combination therapy with

TABLE V

Epididymitis	31	Perineal abscess and fistulæ	13
Joint affections	31	Prostatic abscess	1
Tyson's adenitis	3	Stricture urethra	12
Periurethral abscess	5				

very successful and rapid results. The combined therapy consists of pyrexia induced by dmeleos vaccine with oral administration of sulphanilamide. A course of six injections of dmeleos vaccine on alternate days and oral sulphanilamide produced rapid results. The pain and swelling subsided within a week or ten days and patients were enabled to move the affected joints within a fortnight. Now it is our routine practice to employ the combination therapy in all cases of gonorrhœa with joint complications.

Other complications

In prostatic abscess, cowperitis, periurethral abscess and Tyson's adenitis, sulphanilamide therapy was a distinct failure. These foci of infection had to be dealt with by other methods or surgically, before resorting to chemotherapy. It is our considered opinion that in adnexal infections the value of treatment with the drugs is dubious. In gonorrhœal urethritis complicated with stricture, of which 12 cases are reported, sulphanilamide had no appreciable effect either on the clinical condition or on the bacteriological findings. But preliminary dilatation of the stricture, followed by chemotherapy, resulted in a cure in most of the cases.

Adjuvant treatment

Daily urethral lavage with potassium permanganate lotion was employed in about two-thirds of the cases of gonorrhœa receiving sulphanilamide treatment. A comparison of the results of these cases with those of the other third who had sulphanilamide only without lavage has not convinced us of the necessity of local treatment. Good results were obtained in the latter in as much time as in the former. Medical practices are hard to die, however irrational or empirical they may be, and urethral lavage in gonorrhœa introduced by Janet is one of them.

It is hoped that with further improvement and standardization of the recent chemotherapy, the local or direct attack on the long-suffering urethral mucous membrane with a multiplicity of chemical irritants will be relegated to the limbo of forgotten or forbidden practices. An alkaline mixture was prescribed as a routine to every patient on sulphanilamide therapy, and was found to enhance the effect of the drug, induce diuresis and prevent or diminish the occurrence of the minor toxic reactions. Vaccines were not administered as part of the treatment to any of the patients receiving sulphanilamide, except as a provocative agent in assessing the permanency of cure in treated cases. Hence we have no opinion to offer regarding its value as adjuvant in the new treatment of gonorrhœa. The other additional methods, employed in the treatment of cases under review have already been mentioned under joint and other complications of gonorrhœa.

Standard and tests of cure

The apparently cured cases of gonorrhœa were passed through a number of tests before pronouncing them permanently cured.

- (1) A complete absence of urethral discharge—clear sparkling urine without threads, normal condition of the adnexa, negative bacteriological findings of the urethral scrapings, centrifuged deposit of urine, and the prostatic secretion, a week after all treatment was stopped.
- (2) Clinical and bacteriological examination after sounding and massage—three weeks after cessation of therapy.
- (3) Examination after provocation with vaccines (400 millions).
- (4) In some cases, the same tests were applied after provocation with alcohol or protected coitus or both together.
- (5) These tests were repeated after about six or eight weeks.

In only about 65 of our apparently cured cases could we carry out the repeated tests over a period of six to eight weeks, and declare them permanently cured. The rest of the apparently cured cases did not turn up as directed for examination. But it is presumed from a number of these latter patients who turned up with some other venereal infection weeks and months after their apparent cure and were examined for evidence of gonorrhœa with negative findings, that a large number of these cases remain permanently cured.

Relapses and failures

From among those cases of gonorrhœa who had three weeks' schedule of treatment and who were apparently cured no case of true relapse came under our observation. Regarding the failure of chemotherapy in a percentage of cases we have not been able to study them in detail. From the limited evidence available in our records we endorse some of the causes of failure put forward so cogently by Cokkinis and co-workers (1938). Among the causes of failure, insufficient dosage and early interruption of treatment rank foremost.

The third fruitful cause of failure in our series was the presence of adnexal infection and organic stricture of the urethra. Cokkinis (1937) writes of the existence of 'sulphanilamide prostate', a peculiar painless, smooth enlargement of the gland, as one of the important causes of failure. We have not been able to confirm his observation. Another cause of failure in our records was the existence of a positive Wassermann reaction without any clinical evidence of syphilis in a third of the unsuccessful cases. Whether the positive serology is a mere coincidence or has any inhibitory influence on the chemotherapy of gonorrhœa requires further elucidation. In many of the cases of gonorrhœa which failed to respond to sulphanilamide, we have been noting certain peculiarities in the microscopic picture of smears examined from them. The field shows a

large number of secondary organisms—staphylococci, streptococci and diphtheroids, a considerable number of pus cells with little or no phagocytic action and gonococci in extra-cellular clusters, or scattered over the field exhibiting an atypical morphology and aberrant staining reaction.

Toxic reactions

The toxic manifestations which appear in the course of treatment with sulphanilamide may be mild or serious. The mild reactions, being more common, occur in most of the patients receiving the treatment. The serious effects of therapy, particularly affecting the hæmopoietic functions of the bone marrow, seem to occur on a basis of individual idiosyncrasy, and to that extent are unpredictable. In the incidence of even the milder toxic reactions, there is a large element of capriciousness. Some patients go through the massive therapy of 50 to 60 grammes of the drug without being affected in any way; others show an alarming sensitiveness even after the first dose. Most of our patients complained of minor degrees of toxicity but were able to continue the treatment without mishap. Many of them seem to develop an acquired tolerance to the drug after the first few days. Persistence or recurrence of these mild toxic manifestations called for a halt in the therapy and a careful cytological examination of the blood. The milder manifestations noted in our records were varied and numerous: vertigo, headache, tinnitus, postural ataxia, nausea, disinclination for food, loss of the sense of taste, a sense of fullness in the stomach, mental inertia, inability to concentrate, mental confusion, frequent wet dreams, muscular asthenia. None of these symptoms interfered with the continuance of treatment. A minority of the cases complained of fever, vomiting, abdominal cramps, diarrhoea, paraesthesias, breathlessness on exertion and cutaneous lesions. No case of cyanosis was encountered. In those few cases of breathlessness a spectroscopic examination of the blood failed to reveal any abnormality. Many of these symptoms appeared towards the end of the third week of treatment. It is believed that the blood offers an index of toxicity and in 54 of the cases who exhibited a persistence of these symptoms an examination of the blood with particular reference to hæmoglobin red blood cells and white blood cells content was carried out. In five of these cases who had received a total of more than 50 grammes of the drug, the blood revealed a reduction of total leucocytes and a neutropenia. The drug was discontinued and examination of the blood a month after the cessation of the therapy showed a normal count. Among the drugs tried in our cases the administration of Uleron was conspicuous by the almost complete absence of the toxic reactions. No case of peripheral neuritis, as reported with Uleron by German and other writers, was recorded in our cases. Bannick and others (1938) observed that the same dose of

Uleron and sulphanilamide, when given to a patient, disclosed a low blood and urine concentration with Uleron, while a higher concentration in both appeared with sulphanilamide. This fact may explain the absence of toxic side effects with Uleron.

One case of fatal agranulocytosis occurred in our series.

A male, aged 32, was admitted with gonorrhœal urethritis of a fortnight's duration. Sulphanilamide was orally administered in the following doses:—

- 4 grammes daily for the first week.
- 3 grammes daily for the second week.
- 2 grammes daily for three days in the third week.

During the first week, the urethral infection did not show any improvement and smears and urine were still full of pus cells and gonococci. Towards the end of the week he developed multiple arthritis. The treatment was continued and as he looked ill and there was a slight icteroid tinge of the conjunctivæ towards the middle of the third week, sulphanilamide was stopped. The van den Bergh reaction was reported as 'direct positive delayed and indirect positive faint'. Next day, his temperature shot up to 105.6°F, and he looked extremely toxic. Blood count revealed: total white blood cells 1,500, with complete absence of granular leucocytes. In spite of the usual treatment with nuclein, glucose, etc., he developed signs of patchy consolidation of both lungs, went down hill and expired on the fourth day of illness. He had received 48 grammes of sulphanilamide up to the beginning of the illness.

To be forewarned in future, it is our practice now, after the fatal accident, to do complete cytological examination of the blood after the first week of therapy in all cases treated with one of these drugs.

Gonorrhœa of women and children

The number of women and children treated with sulphanilamide and analysed for the purpose of this study was comparatively small—54 women and 10 children—as the routine use of the drug was started only much later on the female side of the clinic.

The diagnosis of gonorrhœa was based on the finding of gonococci in one or other of the secretions with or without associated clinical signs or symptoms. The 54 women patients comprise 50 uncomplicated urethritis or cervicitis, two cases of acute salpingitis and two with multiple arthritis. The same daily dosage and duration of treatment were adopted as for male patients. Of the 54 cases, treatment had to be discontinued in seven cases on account of certain toxic reactions, and three cases proved resistant to therapy. The remaining 44 patients responded remarkably well to sulphanilamide. A clinical cure was attained in about a week or ten days and bacteriological cure in about a fortnight. No local treatment was given to the majority of the patients except a vaginal douche for the few who had profuse purulent discharge. After the cessation of treatment, most of the women continued to be clinically and bacteriologically negative even after vaccine and post-menstrual provocation; and many of them are still under observation. Three patients, probably of the prostitute class, after remaining negative

for eight to twelve weeks returned with recrudescence of discharge and positive smears, and are considered reinfections, as they confessed to coital exposure. The three resistant cases, on further investigation, were suffering from an associated skencitis. Cauterization of these ducts resulted in cure.

Other things being equal, women seem to be more sensitive to the toxic manifestations to sulphanilamide therapy. Of the seven patients for whom the treatment had to be discontinued three developed high fever, one severe diarrhoea, one peripheral neuritis, one epistaxis and one menorrhagia. All of them completely recovered from these ill effects, but the treatment was not restarted.

Gonorrhœal vulvo-vaginitis of children—10 cases

The ages of the children varied from 2½ to 12 years. The rapid therapeutic response and the remarkable freedom from even the minor toxic reactions were the two special features of sulphanilamide therapy in children.

Of the 10 cases, eight responded to sulphanilamide. One was cured with sulphanilamide and vaginal hormonal therapy and one, a girl of 7½ years, failed to respond even to a heroic total dosage of 54 grammes but was ultimately cured by oral hormone therapy. It was rather difficult to standardize the dose for children and we have erred on the side of excess. The daily dosage in our series varied from 1 to 2 grammes and the best results were obtained with a total dosage of about 15 to 20 grammes in children under six years and 20 to 25 grammes in children between six and 12 years. These apparently cured children are going through their weekly, fortnightly and monthly tests with negative findings. Some of them have been discharged as permanently cured and the rest are still under observation. Our experience with hormonal therapy of gonorrhœal vulvo-vaginitis in previous years was rather disappointing because of the very large percentage of bacteriological relapse after cessation of therapy. It is our impression that a combination of oral sulphanilamide with local hormone treatment will be the ideal method of attaining lasting permanent cures in this otherwise distressing and resistant infection of female children.

Chemotherapy of other venereal diseases

TABLE VII

	Number of cases treated with sulphanilamide
Non-gonorrhœal urethritis ..	24
Chancroids ..	23
Lymphogranuloma inguinale and genito-ano-rectal syndrome. ..	16
Venereal granuloma ..	4

The diagnosis of non-gonorrhœal urethritis was based on the presence of secondary organisms in the urethral smears and urine and repeated absence of gonococci. But most of these patients gave a definite history of antecedent gonorrhœa years ago. All the patients, except two, cleared up rapidly within a week and were free from signs and symptoms. The two resistant cases continued to have cloudy urine and burning on micturition even with massive doses of sulphanilamide for three or four weeks. Smears showed plenty of pus cells and organisms, particularly streptococci in chains. There was a pure growth of *Streptococcus viridans* on culture of the urine in both cases.

Chancroids

Hauschell's (1938) very favourable report on the treatment of chancroids with sulphanilamide induced us to try the drug in some of our numerous cases. Chancroids are fairly prevalent in the city of Madras; an average of 300 to 400 cases either alone or with some other venereal infection attend the clinic every year. Though classed as a minor purely-local infection among the venereal group they cause a lot of annoyance and are tedious to treat. Chancroids under a tight phimotic prepuce are liable to fuso-spirillary infection with rapidly spreading gangrenous ulceration. Old methods of treatment have been unsatisfactory and time consuming. Dmelcos vaccine for which a specific curative action was claimed has proved disappointing. Chancroids of less than two or three weeks' duration, do not respond to the vaccine, and infections of even longer duration are erratic in their behaviour to dmelcos therapy. Twenty-three cases of chancroids were treated with sulphanilamide; of these 21 were males and two females. Two cases had associated painful buboes. Oral sulphanilamide was given to these cases, in 4 grammes daily doses. The therapeutic result was remarkable. There was complete healing of the ulcers in 10 cases by the end of the first week, in eight cases including the buboes by the end of the second week. In three cases it took three weeks' sulphanilamide therapy to produce healing and in two other cases the treatment was a failure. In one of the unsuccessful cases there was a definite history of previous infection with syphilis though the serological reaction was negative. On the whole the results were very satisfactory and as in gonorrhœa it is expected that sulphanilamide bids fair to replace the older clumsy methods in the treatment of infections caused by the strepto-bacillus of Ducrey.

Lymphogranuloma inguinale and genito-ano-rectal syndrome

Sulphanilamide was tried as an experimental measure in 14 cases of lymphogranuloma inguinale in males, and two cases of genito-ano-rectal syndrome in females. Only three cases of the former responded well to treatment and the bubo

completely subsided in about two weeks. The treatment was a failure in other patients.

The drug was also tried as a desperate measure in four antimony-resistant venereal granuloma cases with complete failure.

Summary

1. A clinical report is presented based on our experience with sulphanilamide and its compounds in the treatment mainly of gonococcal infection and secondarily of other minor venereal diseases.

2. The best results are obtained with massive, potentially toxic doses of the drug for a minimum period of three weeks.

3. In gonococcal joint affections, a combined therapy of pyrexia and sulphanilamide seems necessary to attain rapid results.

4. The old-time local treatment of gonorrhœa does not, in our opinion, enhance the therapeutic effect of sulphanilamide.

5. Discontinuance of the drug is indicated in cases which do not show adequate response by the end of the first week; a rest interval and change to another drug of the same group often results in a cure.

6. Small dosage, premature therapy, interruption in the treatment and the presence of adnexal infections are the main causes of failure with sulphanilamide.

7. Uleron is the least toxic of the compounds used in the clinic but its capricious therapeutic action requires further study.

8. Sulphanilamide and prontosil album are the most therapeutically effective drugs of the series.

9. The minor toxic reactions of the sulphanilamide group of drugs seem inevitable and do not necessitate stoppage of treatment. A cytological examination of the blood at the end of the first week of treatment may help to forewarn against the more serious of the toxic manifestations. Persistence or increase in the minor toxic symptoms, severe gastric upset, breathlessness, abdominal cramps, high fever, peripheral neuritis and cutaneous lesions, call for cessation of treatment.

10. A fatal case of toxic agranulocytosis due to sulphanilamide is reported.

11. The results of the treatment of chancroids with sulphanilamide compounds are eminently satisfactory and those of other venereal diseases may be considered failures.

Conclusion

At present gonorrhœa is the most prevalent of the venereal diseases.

The strict parasitism of the gonococcus in man, is the single most important biological factor for its perpetuation and spread. Man has been fighting but a losing battle against its ravages, all these years. Its inevitable association with sex has further contributed to its comparative neglect as a social disease. Even in

and

K. B. PANSE, L.M.P.

House Surgeon

Mayo Hospital, Nagpur

CLAIMS have been made that coliform and gonococcal infections of the genito-urinary tract can be cured by the oral administration of certain drugs of the sulphanilamide group. It was decided to try out this method of treatment. Results have been disappointing and so it is considered desirable to report the results of those cases which could be kept under constant observation and strict bacteriological control. This accounts for the very small number of cases appearing in this communication.

Coliform infections

These were diagnosed and controlled by the aseptic collection of urine without the use of a catheter. Patients who would refuse to permit frequent collection of catheter specimens readily submit to the following method of control, which we have proved to be capable of yielding more sterile specimens than are usually obtained when a catheter is employed. In both sexes, the urinary meatus was thoroughly cleansed with either spirit or a 1 in 20 solution of Dettol in

(Continued from previous column)

the socially advanced countries of the world, where syphilis under modern treatment has tended towards a remarkable decrease, the incidence of gonorrhœa has not shown any decline. Whether the recent discovery of the sulphanilamide compounds is going to sound the death knell of the elusive gonococcus, time alone can reveal. But it may be accepted from evidence, so far available, that the synthesis of these potent chemotherapeutic products is as epoch-making as that of the organic arsenicals, 28 years ago.

water. In males the prepuce was held back and in females the labia were held apart. The patient was then told to pass water and when the stream was flowing strongly a sterile jar was held to catch some of the stream. If the urine was acid, if pus cells were found in it, and if culture yielded a pure growth of coliform bacilli, the case was included in this classification.

Our series consists of eight cases, two males and six females. The two males had been operated upon by one of us (F. A.). In one a stone was removed from the right ureter and in the other an adenoma of the prostate was removed before the infection of the genito-urinary tract was attacked by means of sulphaphenylamide. The six females suffered from chronic pyelitis or cystitis. Two of them had already contracted phthisis. Skiagrams had been taken to exclude the presence of urinary calculi.

The urine was in every case kept alkaline during the administration of 3 grammes of sulphonamide-P or Prontosil album daily, divided into three doses, for seven days. No case was cured. In one of the females only did the drug appear to have any inhibitory effect on the organisms. None of our patients weighed more than 110 lb. and only two weighed over 100 lb., so that the dose of the drug would appear to have been adequate.

Gonococcal infections

These were diagnosed by the finding of Gram-negative diplococci in stained films of material taken from some part of the genito-urinary tract.

Our series comprises nine cases, three males and six females, all of whom were treated with Uleron.

One male had an acute anterior urethritis of ten days' duration when treatment was commenced. The other two males suffered from chronic anterior and posterior urethritis and chronic prostatitis. The six females all suffered from chronic cervicitis, only one of them was pregnant.

All the patients were under 110 lb. in weight. Each patient was given 3 grammes of Uleron daily, divided into three doses, for four days, as one course. An alkaline mixture was given with the Uleron. No other treatment was employed but the patients were kept at rest. One patient had six courses separated by intervals of one week, one patient had four courses and the remainder had three courses.

No patient was cured. While Uleron was being administered the gonococci disappeared from the films, but on the withdrawal of the drug the organisms re-appeared.

Our thanks are due to Messrs. Havero Trading Co., Ltd., Bombay, who, with great generosity, supplied us with a free sample of 640 grammes of Uleron. It is therefore a matter of deep regret that we are unable to report satisfactory results.

INVESTIGATION INTO THE NATURAL BREEDING PLACES OF THE *SIPHUNCULINA FUNICOLA* FLY, IN ASSAM

By C. S. P. HAMILTON, D.S.O., M.R.C.S., L.R.C.P.

Introduction

THE reason for carrying out this investigation into the natural breeding places of the *Siphunculina funicola* fly is twofold. Firstly, because accurate knowledge of the life history of this fly is considered of importance, owing to its probable connection with the spread of diseases, such as epidemic conjunctivitis and possibly yaws, and secondly, because the eye-fly from April to October is a definite nuisance to everyone in this district.

For two years, up to the 24th March, 1937, the writer carried out an investigation, during his spare time, into the question of the breeding habits of the *Siphunculina funicola* fly in the area of the Juri Valley Medical Association, in the district of Sylhet, Assam (Hamilton, 1938) (Sylhet on the map is situated 24° 55' N.; 91° 59' E.).

On the 24th March, 1937, this research was started in earnest, as up to that time the investigation had produced no definite result. It was clearly realized that if it was hoped to obtain accurate information the research must be a very thorough and a continuous one.

Epidemic conjunctivitis

There seems little doubt that in this district epidemic conjunctivitis is a contagious disease, and that the contagion whether septic in origin or due to a specific organism, not yet discovered, is carried by the *Siphunculina funicola* fly, or eye-fly, by which name it is commonly known.

In this district we find the disease prevalent from March to the end of September. It is during the same period we find the eye-flies in their greatest numbers. The disease itself is a serious one, not only because of the discomfort and the great pain it causes to sufferers, but also because of the complications arising from the disease. Even amongst those treated we find an 'after complication' rate of 1.8 per cent to 1.9 per cent.

Further, it is a serious economic factor. Each sufferer must have an attendant, and the average number of days of attending hospital over a

(Continued from previous column)

Our thanks are also due to Colonel D. H. Rai, I.M.S., Inspector-General of Civil Hospitals, Central Provinces and Berar, for permission to publish these results.

Note.—It is of course important to report failures as well as successes in treatment with new drugs for which claims are made. This series is, however, a small one and a 'mixed' one. Failures are sometimes due to the unsuitability of the cases treated or of the methods adopted, rather than to the inefficacy of the drug. Readers are referred to a note in our Current Topics section (p. 240) in which the reasons for the failure and apparent failure of Uleron in certain cases is discussed.—EDITOR, I. M. G.

series of 2,500 cases worked out at just over one week. In the tea industry, this disease occurs at the busiest period of the year, thus the loss of labour, at such a time, causes a good deal of inconvenience. In the year of drought in 1937, there were 2,227 separate cases of conjunctivitis in the Juri Valley from 1st March to 31st September. This figure will give an idea of how serious the problem may become.

Previous investigations

Evidence had been collected from casual observers, such as Indian clerks living in *bashas*, bungalow residents, and the labourers themselves, that the thatch of houses was the most likely breeding place of the *Siphunculina funicola* fly.

Some of the local inhabitants in the district considered this fly to be breeding in soil, others thought it might be in decaying vegetation or ammoniacal soil of cattle sheds. We know that in other districts there is scientific evidence incriminating certain of these breeding places.

Patton (1921), referring to work on the breeding habits of this fly carried out in 1914, stated that large numbers of these flies found on pieces of straw, string, cobwebs, etc., hanging from the roof of the leather factory at Saidapet, Madras, were placed in test tubes. Eventually, some of these flies laid eggs, and, from some of these eggs, adult flies were hatched out. It was then thought that, as the factory was situated close to a plantation of palmyra palms, and on the ground around these palms a number of palm nuts were found rotting, perhaps the *Siphunculina funicola* fly laid her eggs there, and that this was its natural breeding place. However, no egg, larva or pupa of the fly was found there. Patton goes on to say that recently in the Nilgiri Hills, larvæ simulating the eye-fly (*Siphunculina funicola*) had been found amongst decaying banana leaves, but that the fly had not been bred out from these larvæ.

Syddiq (1938) in Hyderabad reports finding the natural breeding place of the *Siphunculina funicola* fly, in that area, to be in contaminated soil. Strickland (1938) also states that Jepson and Pinto of the Ceylon Government Agricultural Service, bred the flies artificially on a variety of dead organic matter. D. N. Roy (1928) found that these flies were breeding naturally in earth of cattle sheds.

Present investigations

In this district we have found no evidence that the *Siphunculina funicola* fly breeds in damp or ammoniacal soil, in decomposing vegetation, or in manure of cattle or horses. We base this observation on the fact that, from the date 24th March, 1937, when this research was commenced, up to the time of writing this article, 1st November, 1938, we have examined hundreds of bottles of specimens and have never found the eggs, larvæ or pupæ of the *Siphunculina funicola* fly in any material except thatch grass. However, we have often found the young forms of

other varieties of flies in ammoniacal soil, and bred out adult flies from them. (The specimens examined included ammoniacal soil from cattle sheds, soil from latrines, and drains, decomposing vegetation, and soil found in galleries of ant heaps.)

Since . . . research, not only have we found *Siphunculina funicola* fly on many occasions in its young forms (eggs, larvæ, pupæ) in thatch, but we have succeeded in breeding out the adult fly from these young forms, and often on the original pieces of thatch they were found in, without the addition of any extra media; for purposes of hatching flies in connection with this research, we use a funnel which was suggested to us by Professor P. A. Buxton (Hamilton, 1938)

Fig. 1.—Showing funnels suggested by Professor Buxton for breeding flies from various media.

of the School of Tropical Medicine, London (see figure 1). Up to August 1938 we had only been able to breed a few adult *Siphunculina funicola* flies at a time, from various collections of eggs and larvæ found in thatch; the greatest number bred from a single specimen of thatch containing the young forms of this fly were nine.

The following important experiment was carried out on the 2nd February, 1938. A sample of ammoniacal soil was divided into two portions, one was boiled for one hour (actual boiling) and the other left unboiled: from the unboiled portion many flies were hatched out, none of these flies proved to be *Siphunculina funicola*. On the boiled portion we put six *Siphunculina funicola* eggs, found in thatch, and from these bred two *Siphunculina funicola* larvæ

and pupæ, eventually one adult *Siphunculina funicola* fly hatched out on 7th March, 1938.

Specimens of these flies were sent to the London School of Hygiene and Tropical Medicine, and our findings verified.

On 29th August, 1938, a few pieces of thatch were collected from a bungalow, and on these we found a number of *Siphunculina funicola* eggs and live larvæ. On this small collection of grass—seventeen live adult flies were bred out, and in addition three freshly hatched but dead ones were found in the tube. A few of these flies were sent to Professor Buxton and identified by him as *Siphunculina funicola*. These same flies were also sent to Dr. Curtis W. Sabrosky in the U. S. A. to be critically examined by him. He wrote to say that he had carefully compared them with the specimen from which de Meijere originally described the species and that he identified them as *Siphunculina funicola*. Dr. Sabrosky is accepted as the leading authority on the systematics of the *Oscinids*. A photograph of one of these flies hatched out in this experiment is given in this article (figure 2).

Fig. 2.—*Siphunculina funicola* fly actually hatched from eggs found in bungalow thatch (note well-marked 'humeral cross vein' joining subcostal to costa).

The strong point in the argument against thatch grass being a natural breeding place for the *Siphunculina funicola* flies was the fact that, up to then, so few adults had been bred from eggs or larvæ found in thatch, so that this experiment is important. When one realizes that in a few strands of thatch grass taken from a bungalow roof, no less than twenty flies were bred, it does not take much imagination to think of the number of flies breeding in the thatch of hundreds of tea garden houses. At the same time as the *Siphunculina funicola* flies were bred we hatched out numerous flies from ammoniacal soil of cattle sheds, however, not one of these flies was a *Siphunculina funicola*; they all proved to belong to the *Borboridæ* family. I sent these soil flies to the London School of Hygiene and Tropical Medicine, and they upheld the identification as being *Borboridæ*.

An interesting fact in the breeding habits of these flies in thatch is that, in the majority of

cases, dead flies in disintegrated forms were found together with collections of fly eggs, the whole being laid in a blackish mass entwined in a web. The mass may assume a definite roundish shape, become semi-solid, and eventually act as a 'cocoon mass', harbouring a larva or pupa. The writer has dissected several of these masses and found typical larvæ or pupæ in them; he also dissected out an eye-fly from a pupa found in one of these black masses. This blackish material found on pieces of sun-grass is probably formed from excreta or secreta from the flies themselves. At first it was thought to be due to soot, and the strands of grass covered by this material we called sooty strands. However, its origin from sooty deposits was soon disproved, as pieces of thatch covered with the same blackish substance were found in the eaves of a bungalow in which no fires exist, and therefore there is no soot. Pieces of binding wire found in thatch roofs have been seen to be covered with this black substance, and harbouring a number of live and dead *Siphunculina funicola* flies. On one strand of wire we found a typical hard blackish nodule akin to the nodules described above (figure 3), and on

Fig. 3.—Typical 'cocoon type of mass' (black semi-solid) found hanging on a wire outside a bungalow. From many masses, similar to this, *Siphunculina funicola* in young forms have been dissected out. On this actual wire many *Siphunculina funicola* flies were found and the whole wire was covered with a black pultaceous substance.

the same wire, dead and disintegrated *Siphunculina funicola* flies, and many of their eggs were found lying in this blackish substance. One might say the majority of pieces of house thatch examined were covered with this blackish substance, often found to be harbouring the disintegrated forms of the flies, plus their eggs, and in many cases their larvæ. It is certainly not necessary for the larval, and pupal stages, to be encased in this black nodule, as they have more often been found to be lying in the folds of the thatch grass; nevertheless, on many occasions we have found them as described above, namely, encased in these nodular masses (figure 4).

On 30th April, 1938, thatch containing *Siphunculina funicola* eggs was collected (8 pieces of thatch averaging $\frac{3}{8}$ inch \times $2\frac{1}{2}$ inches long); from this three adult *Siphunculina funicola* flies were hatched out on 31st May, two on 11th June, and from that date until 1st November no further flies were hatched out. (I think actually the flies must have hatched out on the night of

31st October, as we examined the tube in the morning of 1st November). This means that fly eggs in thatch are viable for a very long period. In the funnel tube in which we hatched out these flies on 1st November, we also found pieces of pupal skin, dried up and dead *Siphunculina funicola* larvæ, and several eggs, some dried up, but some looked quite healthy.

Description of *Siphunculina funicola* (eye-fly)

The species was originally described by de Meijere.

It is an insect about 1/16th inch in length and is almost black in colour except the wings.

Entomological.—This fly belongs to the *Oscinidæ* family. The male fly is to be distinguished from the female one by the absence of ovipositor.

It possesses head, thorax, two pairs of wings and three pairs of legs. On the head there is a pair of antennæ from the third segment of which arise a pair of very finely feathered aristæ. The proboscis has a stout hook-like process at the tip.

The anterior pair of wings is shining in colour, whereas the posterior pair, the halteres, are not covered with squamas.

The venations of the wings are as follows:

There are four longitudinal veins; the transverse or cross vein, connecting the costa with sub-costa (humeral cross vein), is very prominent and situated at right angles towards the basal area. The vein joining the second to the third is called sectorial cross vein, and that joining the third to the fourth, the radio-medial cross vein. There are three pairs of legs. In the front pairs the femur is black, the tibia and the tarsi are golden in colour without interruption of any other colour.

In the mid and hind pairs—femurs and tibiæ are black and only the tarsi are golden without interruption of any other colour. The coxa femoral joints are golden in colour in each of the three pairs; but the knee joints are golden in colour in the mid and hind pairs of legs only.

Eggs.—The egg measures about 0.5 mm. in length, is whitish in colour, oval and boat-shaped, one end being bluntly rounded off, and the other pointed (figure 5). One side is slightly concave and the other convex.

The surface of the egg is marked by a number of longitudinal striations.

Larvæ.—A mature larva is about $\frac{1}{8}$ inch in length, yellowish white or creamy white in colour, and consists of 13 segments. The head end is

tapering while the posterior end is gradually enlarging and is truncated. The antennæ consist of very small blunt hairy projections only. The anterior spiracles project from the sides of the thorax some distance behind the thorax and each consists of a stalk with five finger-like processes. The posterior spiracles project some distance from the dorsal surface of the eighth abdominal segment.

Pupæ.—The pupa (figure 6) has 10 segments and is slightly shorter in length, but is bigger in size than the larva. It is amber in colour. One surface is comparatively more convex than the other. The anterior end is narrower than the

Fig. 4.

posterior, and the spiracles project from the posterior end.

Patton says that one fly can lay as many as 60 eggs; up to now we have only been able to dissect as many as 40 eggs from a single fly.

Fig. 5—Eggs of *Siphunculina funicola* lying in situ on thatch grass.

The fact that the females lay eggs in batches of 5 to 10 is obvious. We have a few flies mounted actually in the position of laying their eggs in

thatch grass and in one of them we found 10 eggs laid in one batch (figure 7).

Fig. 6.—Typical *Siphunculina funicola* pupa in thatch from which a fly had just hatched out.

Duration of phases in life cycle.—In favourable weather conditions the whole life cycle takes about three weeks to complete, but it varies greatly with the variation of the climate.

Fig. 7.—Showing batch of 10 eggs laid by the fly.

From larva to adult fly average 7 to 8 days. Actual hatching dates in different experiments were as follows:—

- | | |
|--|-------------------|
| (a) From egg to fly | .. 24 to 25 days. |
| (b) From larva to fly | .. 9 days. |
| (c) From larva to fly | .. 7 days. |
| (d) From larva to fly | .. 8 days. |
| (e) (Media used here was boiled cow-dung on which were placed eggs hatched in thatch). | |
| (i) From egg to larva | .. 10 days. |
| (ii) From larva to pupa | .. 14 days. |
| (iii) From pupa to fly | .. 12 days. |

It must be remembered that these hatching experiments—*a, b, c, d, and e*—were from eggs found in thatch, and not from eggs laid by

'EYE-FLY HOUSE'.

Fig. 8.—The special house erected beside the Juri Valley Medical Association Laboratory, in which some of the experiments were carried out.

flies in captivity. The age of the eggs was unknown, therefore the length of time from the egg to the larva is not given, as it could not be accurately estimated.

Summary

An investigation was carried out into the breeding habits of the *Siphunculina funicola* fly. It was found that in the Juri Valley areas, South Sylhet, this fly breeds in thatch of houses, especially in the thatch of the eaves of these houses. The whole cycle from the egg to the adult fly takes place in the thatch grass. The flies hatched in thatch from eggs after a period of six months.

In ammoniacal soil and decomposed vegetation, it was proved that *Borboridæ* breed in numbers, but no evidence was found of the *Siphunculina funicola* breeding in this type of soil or in decomposed material.

Conclusion

That in the Juri Valley area of Assam, the only place the *Siphunculina funicola* breeds is in thatch of houses. Ammoniacal soil is therefore not a dangerous medium, as far as this fly is concerned, in the Juri Valley.

This research has been brought to a successful climax for two reasons, firstly, because it was a daily investigation and prolonged over a long period; secondly, because it was being conducted on the spot and specimens were therefore available in a fresh condition.

Acknowledgments.—The writer wishes to acknowledge his debt of gratitude to the following:—Professor P. A. Buxton, of the London School of Hygiene and Tropical Medicine, whose collaboration was of the utmost value, Drs. H. N. Chowdhury, L.M.P., K. N. Das, L.M.P., N. C. Deb, L.M.P., for their untiring work throughout varying stages of the investigation. To Dr. S. K. Dutta, L.M.F., L.T.M., Malarialogist, Central Laboratory, Juri Valley Medical Association, for his help in examination of the entomological specimens. Last but not least the whole staff of the Central Hospital, Juri Valley Medical Association, and especially the chief laboratory assistant Sreejut Abinash Chakravarty, who was in charge of the preparation of the microscopic specimens.

APPENDIX A

List of total number of specimens examined:—

Material	* Number of specimens
Thatch grass	525
Ammoniacal soil	145
Fresh soil	23
Materials other than thatch grass and ammoniacal soil, e.g., decomposing vegetation, leaves, banana tree leaves, etc.	71
TOTAL ..	764

* Bottles or tins of specimens sent for examination—one bottle or tin often contained a great number—50 or even more separate specimens for microscopical examination. In all some thousands of specimens were examined microscopically, as the investigation was continuous and daily carried on throughout the whole period from 24th March, 1937 to 30th November, 1938.

APPENDIX B

List showing number of times eggs, larvæ and pupæ simulating those of the young forms of *Siphunculina funicola* were found in thatch grass

Eggs found	340 times
Larvæ found	49 "
Pupæ and pupal skin found	50 "

In all on 28 occasions adult live *Siphunculina funicola* flies were hatched out from young forms found in thatch, giving a total of 56 adults.

THE QUALITY OF MEDICINAL COD-LIVER OIL AND ITS PREPARATIONS ON THE INDIAN MARKET

By N. K. IYENGAR, M.Sc. (Bom.)
and

B. MUKERJI, M.B. (Cal.), M.D., D.Sc. (Mich.)
(Biochemical Standardization Laboratory, Government of India. All-India Institute of Hygiene and Public Health, Calcutta)

Introduction

COD-LIVER oil is the fixed oil expressed from the fresh liver of the codfish (*Gadus morrhua*, Linn.) by the application of low pressure steam at a temperature not exceeding 85°C., and freed from solid fat by filtration at about 0°C. It occurs as a pale yellow liquid with a slightly fishy but not rancid odour, and a bland, slightly fishy taste. Amongst fatty oils, cod-liver oil occupies a peculiar position chemically, for it contains, besides the ordinary types of fat, glycerides of very non-saturated fatty acids (largely those of Clupanadonic acid, $C_{22}H_{34}O_2$ and of a highly unsaturated acid containing 18 or 20 carbon atoms), which are not found in other oils. The unsaturated character of the fats is an important factor, as on this depends the comparatively easy assimilation and metabolic oxidation of the oil. The unsaturated fatty acids are therefore considered to be of definite therapeutic value. Apart from these, cod-liver oil contains vitamins A and D and these are supposed to be chiefly responsible for its medicinal importance.

Adulteration of cod-liver oil

The best cod-liver oil is extracted from the fat livers of the sea-cod and other species of cod caught in the early part of the winter when this fish makes its way in from the sea to the west coast of Norway, Greenland and Newfoundland, etc., to spawn upon the banks lying off these coasts. Because of the polar ice cap, the small craft found in the coastal waters of Northern Europe cannot reach the fishing grounds on which the best cod is caught. Special types of trawlers are required for such fishing operations. Many fishing fleets not equipped with such trawlers are therefore forced to carry on operations in areas where, along with the cod caught, large numbers of haddock, ling and other fish are usually present. Under ordinary conditions, all the fish livers are pooled together and boiled for extraction of the oil. If the catch contains a mixture of different types of fish it is naturally difficult, unless special precautions are taken, to ensure the production of a uniform grade of cod-liver oil. Such mixed oil is often offered for sale in bulk by wholesale traders and importers. Commercial brand, 'coast cod oil' for instance, is really a mixed fish-liver oil which may have been obtained from any fish, e.g., cod, shark, dogfish, etc., which the trawlers' nets bring up from the open sea. If such foreign

liver oils are mixed in large proportions, the quality and the medicinal virtues of cod-liver oil will naturally be affected. There is another important factor which can bring about a poor quality of cod-liver oils. If the fresh livers obtained from the cod are not immediately boiled and extracted, or are not properly stored in refrigerated chambers, they are likely to be decomposed before long. If decomposed livers are used in the preparation of the oil, the resultant product shows a rich content of free fatty acids, and is likely to lose much of its medicinal efficiency. Apart from these difficulties inherent in the cod fishing industry, there are a number of other ways by which cod-liver oil of commerce may be adulterated. The mixture with cheap and bulky oils derived from 'menhaden', 'seal', 'porpoise', etc., are reported to be not an uncommon occurrence. Rosin oil and cheap-grade mineral oils are also known to be sometimes mixed with cod-liver oil.

All cod-liver oil and its preparations found in India are imported from foreign countries. Because of the widespread prevalence of deficiency diseases in India, cod-liver oil and its preparations are in great demand. According to the figures given in the sea-borne trade statistics of British India, nearly 100,000 pounds of cod-liver oil are annually imported into India at a cost of approximately Rs. 1,50,000. It is either imported in bulk from outside, bottled by local manufacturers and marketed under their own labels and trade marks, or finished preparations of foreign pharmaceutical manufacturers are directly imported.

TESTS FOR PURITY OF COD-LIVER OIL

To prevent the medicinal use of adulterated and low-grade cod-liver oils, the *British Pharmacopæia* 1932 has adopted the following standards for pure cod-liver oil :—

Sp. gravity (15.5/15.5)—0.922 to 0.929.

Refractive index at 40°—1.4705.

Acid value not greater than 1.2.

Saponification value—180 to 190.

Unsaponifiable matter—not more than 1.5 per cent.

Iodine value—155 to 173.

The oil should remain bright when cooled to zero and kept at that temperature for three hours. It should contain in 1 gm. not less than 600 units of vitamin-A activity and not less than 85 units of antirachitic activity (vitamin D). The *B. P.* 1932 states that it should comply with the antimony trichloride test for the presence of vitamin A. This test prescribes a lower limit of 6 Lovibond Blue Units.

The tests for purity and the new official standards for vitamin values in the *British Pharmacopæia Addendum* 1936 ensure an excellent quality of cod-liver oil. Any departure from the limit would indicate either a deterioration of the quality of the oil, or an adulteration with foreign oil of animal or mineral origin. It must be remembered, however, that

no opinion as to the genuineness of a sample of cod-liver oil can be expressed unless it is subjected to all the standard tests prescribed. Conclusions as to the purity or otherwise of a sample drawn from individual determinations of specific gravity, saponification value, iodine value, etc., are open to serious criticism. Thus, the specific gravity determination alone affords no reliable indication of the presence of other fish oils in cod-liver oil samples. The refractometer, again, is of limited use except as a rapid sorting test. A low saponification value of an unknown sample affords an indication that there may be some adulterant in the form of shark-liver oil or dogfish-liver oil. If this low saponification value is associated with a high content of unsaponifiable matter, the presumption of such adulteration becomes very strong. However, the allowable ranges given in the *British Pharmacopæia* 1932 for saponification values are fairly wide (180 to 190) and it is not unlikely that even moderately adulterated samples may conform to the standards in this respect. The same remark applies to the iodine value determinations. The oils from decomposed livers usually show lower iodine values but the *Pharmacopæia* range for iodine values is again fairly wide (155 to 173) and moderately adulterated samples may not be detected if an opinion is offered on this determination alone. The free fatty acid in fresh cod-liver oil should be very trifling in amount. In inferior, old and partially decomposed specimens, the fatty acid value may go higher. The unsaponifiable matter in genuine cod-liver oil contains cholesterol and usually does not exceed 1.5 per cent, as specified in the *British Pharmacopæia* 1932. A higher percentage may indicate the presence of any foreign fish oil, e.g., oil from shark, dogfish, sunfish, etc., mineral oil or rosin oil. An abnormally high value has been ascribed to the presence of porpoise oil. It is impossible therefore to detect definite adulteration or the nature of the adulterant by individual tests. In the survey that has been carried out in this laboratory, the oils have been examined for all their properties strictly according to the methods laid down in the *Pharmacopæia*. A few additional tests mentioned in recent literature were also employed to detect, if possible, the nature of the adulterant. The conclusions drawn are based on the interpretation of all the findings collectively.

PROCEDURE

(a) *Collection of samples.*—In order to obtain a representative picture of the quality of cod-liver oil and its preparations available in the Indian market, samples were obtained from practically all the provinces of British India. In this difficult work, the heads of the medical and public health departments of the provinces co-operated at the request of the Central Government. The samples were received either in sealed original containers or in sample phials containing about 2 oz. each, which were filled in

the presence of a medical officer and sealed properly before mailing. Through the courtesy of the Collector of Customs, Calcutta, samples were also obtained from the customs storehouse within a few days of their importation into the Calcutta port. A few samples were also purchased at random from the open market by the officers of the laboratory. The samples on which the following report is based took nearly two years to collect. The names of the manufacturers were obtained in most cases through the courtesy of the senders but information regarding the dates of purchase and the conditions of storage of the samples were not available in all cases.

(b) *Methods of analysis.*—The analytical methods employed are essentially those described in the *British Pharmacopœia* 1932. Slight modifications were made in favour of more improved methods. In the iodine value determinations, the pyridine-dibromide technique of Rosenmund and Kulmhenn (1923) was employed. This method is generally considered to yield more accurate figures than those obtained by the Wij's method. The method used for preparing, extracting and testing the unsaponifiable fraction of each oil was that described by Smith and Hazley (1930). For the estimation of the vitamin-A content, the direct blue value of the oil was determined by the *B. P.* method (1932), a Lovibond tintometer with artificial light attachment being used. Though the *B. P. Addendum* 1936 recommends either the biological or the spectrographic determination of the vitamin-A content of cod-liver oils, the direct blue value determination is still considered useful for comparative work in sorting oils as good, bad, and indifferent (Coward, 1935). Suitable dilutions were made so that the blue colour produced after the addition of the antimony trichloride reagent could be satisfactorily matched by Lovibond blue between 4 and 6. The values thus obtained for each oil were then converted into the customary Carr-Price value, i.e., the blue value of 0.04 gm. of oil. As vitamin A is now known to be present in the unsaponifiable fraction of the oil, the blue value of this fraction was also determined simultaneously in some cases in order to find out the ratio between the blue value of the unsaponifiable matter and the blue value of the original oil. About 15 samples were subjected to this test and the ratio in all the cases was round about 1.6, agreeing closely with the values reported by Evers (1934). Through the courtesy of the biochemistry department of the All-India Institute of Hygiene, the vitamin-A potency was also estimated in a few specimens by studying the absorption band of the oil in the ultra-violet region at a wave length of 328μ using an ultra-violet spectrograph. The biological estimation of vitamins A and D was not attempted for want of a suitable rat colony.

The 'chill test' was performed by keeping the oils in a clean dry test tube and maintaining it at 0°C ., in the 'biological chamber' of the

refrigerator for three hours, at the end of which period the turbidity, if any, was observed. Common (1937) has reported that the presence of mineral oil as an adulterant in cod-liver oil can be readily detected by exposure of the sample to be tested to the ultra-violet light under the quartz mercury-vapour lamp. The appearance of a bright blue fluorescence, instead of a bright grass-green fluorescence which is characteristic of pure cod-liver oil, indicates the presence of mineral oil. The presence of sperm oil, if in considerable quantities, can also be detected by the appearance of a greenish-blue fluorescence. The samples were submitted to this test also. In none of the samples, however, could the presence of either mineral oil or sperm oil be detected.

Results

The results are represented in table I. Altogether 100 samples were analysed of which two were vitamin-A concentrates, one an emulsion of cod-liver oil and another an extract of malt with cod-liver oil. In table II, an abstract of some of the findings is presented. It will be seen that 64 samples or 64 per cent of the lot were found not to conform to the *B. P.* standards. In almost all these suspicious samples, the values were always in excess of the maximum prescribed by the *B. P.*, indicating that the samples were either old, inferior, or prepared from partially decomposed livers. A few samples failed in all the tests indicating definite adulteration with other fish oils of very inferior grade. The high unsaponifiable matter in some of these lends further support to this conclusion. As many as 25 samples were deficient in vitamin-A content and 4 samples of this group showed absolutely no vitamin A at all. It was observed that although some of them conformed to most of the chemical tests, yet they were deficient in vitamin A, indicating that they were genuine cod-liver oils but of low vitamin-A potency. Most of these were further found to be different in physical appearance and were either of a different colour to a brand of pure oil, or distinctly rancid. A classification of the samples analysed according to their sources of origin (from the labels on the containers) has been presented in table III. Thirty-one samples were obtained directly from countries outside India and of these 16 (51.6 per cent) samples failed to conform to the *B. P.* standards and four specimens were deficient in vitamin-A potency. Out of 65 preparations of local origin, presumably bottled from cod-liver oil imported in bulk, 42 samples failed to satisfy the *B. P.* requirements and 19 showed a poor vitamin-A content. The high percentage of oils with low vitamin-A potency among the specimens marketed by manufacturers in India raises the interesting question that the conditions of storage in the tropical climate may play an important part in the maintenance of the quality of cod-liver oils. Vitamin A is apparently much less stable under

the conditions of storage and distribution existing in India. However, as the data regarding the dates of manufacture and conditions of storage and distribution of these oils were not available, no definite pronouncement could be made on the subject. Attempts are being made to work out this aspect of the problem.

Discussion

The importance of cod-liver oil and its preparations in medical practice is too well known to need special mention. As has been already stated, cod-liver oil is not only a rich source of vitamins A and D, but contains in addition a large proportion of unsaturated fatty acids, all of which are of definite therapeutic value. Vitamin A is known to-day to be essential to growth, vision, and the maintenance in normal condition of certain specialized tissues of the body. Its deficiency produces morbid changes in the cornea (keratomalacia) which may, in extreme cases, lead to loss of vision. In addition, vitamin A is also essential for the normal behaviour of the retinal organs and for the formation of rhodopsin (visual purple). Vitamin

D has also undoubted antirachitic properties. Cod-liver oil is one of the few medicines universally used in diseases where a deficiency of vitamins A and D is suspected. It is also used for its food value in wasting diseases and in increasing the general resistance of the body against infective conditions.

In view of such important and vital properties of the oil, it is of great importance to ensure an excellent quality of cod-liver oil for the consumer. The survey that has been carried out in this laboratory reveals a very unsatisfactory state of affairs from the point of view of public health. While it is probable that many samples may have lost their vitamin-A potency due to bad storage and exposure to the hot and humid climates of India, it is not improbable that wilful adulteration is also going on in the drug market. It may be pointed out in this connection that similar surveys have been carried out in Great Britain by Dyer (1933) and by Evers (1934) and in the United States by Nelson and Walker (1932). Both Dyer and Evers found that the cod-liver oils offered for sale in Great Britain were generally of a good quality and most of the samples tested showed a 'blue value' ranging between 6 and 50. Nelson and Walker's findings also revealed a fairly satisfactory situation in the United States. The reason for this difference in the quality of medicinal cod-liver oils is probably due to the fact that in both these countries the regular testing of oils at the port of entry tends to eliminate low-grade oils from the open market.

It is desirable that the medical practitioners should be aware of the poor quality of cod-liver oil and its preparations on the Indian market. The consumers in general are ignorant of the quality of the preparations at the time of buying. The public can only be protected by the enactment of some legislation insisting on a regular and thorough testing of all brands of medicinal cod-liver oil imported, stored and distributed in India.

Summary

One hundred samples of medicinal cod-liver oil and its preparations, with both foreign and indigenous labels, obtained from the civil hospitals, customs department and the open market in different provinces of India were subjected to analyses for their purity and vitamin-A content, according to the methods and standards laid down in the *British Pharmacopæia* 1932 and in other standard books of reference.

Sixty-four samples (64.0 per cent) out of the total failed to satisfy the B. P. requirements. Twenty-five samples were found to be deficient in vitamin A and four samples out of this group were completely devoid of vitamin A.

This survey, the first of its kind in this country, reveals a very unsatisfactory state of affairs in the drug market in India. The public

OBSERVATIONS ON SOME IMMUNOLOGICAL ASPECTS OF LEPTOSPIRAL INFECTIONS

(Part I)

By B. M. DAS GUPTA

(From the Department of Protozoology, School of Tropical Medicine, Calcutta)

Durability of passive immunity induced in the guinea-pig following the infection of anti-leptospira serum

In leptospiral infections in man and animals, about a fortnight after the attack, a substance appears in the blood, which is capable of protecting susceptible animals against infection with this organism. An anti-serum of high potency can also be prepared artificially by immunizing horses, rabbits, etc., with cultures of leptospira. With a view to ascertaining the extent of the period of immunity acquired by the injection of anti-sera obtained from different sources, the following experiments were performed:—

Materials and methods

The serum, obtained from a severe human case of leptospiral jaundice 96 days after an attack, was used for the first series of experiments. The agglutination titre of this serum against the homologous strain was 1:10,000.

(Continued from previous column)

is unaware of the poor quality of such medicines and the doctors prescribing the drug has no means of knowing what is inside the bottle. Only governmental control, as it exists in the progressive western countries, can protect the interests of the consumer and the medical practitioner prescribing cod-liver oil and its preparations to their patients.

Acknowledgment

The authors wish to express their gratefulness to Brevet-Colonel R. N. Chopra, M.D., Sc.D., F.R.C.P., C.I.E., K.H.P., I.M.S., Director, Biochemical Standardization Laboratory, for his interest in the work, for his valuable advice and guidance throughout the course of this research and for his kind permission to publish the paper. A preliminary communication was made at the clinical meeting of the Medical College Reunion in December 1938.

For the second series, anti-serum was prepared by immunizing an adult male rabbit weighing 2,800 grammes by intravenous injections of rich living cultures of the organism recovered from the above case at intervals of five days, in doses from 2 c.cm. to 8 c.cm. The total number of injections was six. The test bleeding was made

seven days after the last injection. The serum reacted with the homologous strain to a titre of 1:100,000. Two days later, the animal was bled to death and about 11 c.cm. of serum were obtained. For the third series of experiments, 'Wellcome' brand anti-leptospira serum, prepared at the Wellcome Physiological Research

TABLE I
Experiments with anti-serum of human origin

Serial number of guinea-pigs	Weight in grammes	Date of inoculation of anti-serum	Date of infective inoculation	Results
1	218	24-1-38	25-1-38	Remained alive and well for 15 days.* Do. Do. Do. Do. Do. Do. Do. Do.† Do.†
2	210	25-1-38	27-1-38

8	219	25-1-38	15-2-38	
9	243	25-1-38	18-2-38	
10	242	25-1-38	21-2-38	
11	213	25-1-38	24-2-38	Died of leptospiral infection on 28-2-38.
12	198	25-1-38	26-2-38	Marked jaundice and hæmorrhages from nostrils and anus on 28-2-38 and died next morning. Blood positive for leptospira on 29-2-38 and the animal died two days later.

* Animals that remained alive and well for 15 days were considered sufficiently protected against the infection.

† As a suitable culture was not available at the time, the animal was inoculated with 2 c.cm. of infected guinea-pig's liver emulsion. The control animal also received similar inoculation.

TABLE II
Experiments with immunized-rabbit serum

Serial number of guinea-pigs	Weight in grammes	Date of injection of anti-serum	Date of infective inoculation	Results
1	210	2-4-38	12-4-38	Remained alive and well far beyond the usual fatal period. Do. Do. Do. Do.
2	199	2-4-38	22-4-38	
3	216	2-4-38	2-5-38	
4	215	2-4-38	12-5-38	
5	211	2-4-38	24-5-38	
6	248	2-4-38	29-5-38	Died of leptospiral jaundice on 29-5-38. Developed leptospiral infection.*

* On the fifth day of inoculation the animal showed marked jaundice and leptospiræ were present in the peritoneal fluid. It was then killed to provide material for demonstration to the students.

TABLE III
Results of the inoculation of the commercial anti-leptospira serum (B. W. and Co.)

Serial number of guinea-pigs	Weight in grammes	Date of injection of anti-serum	Date of infective inoculation	Results
1	232	4-6-38	9-6-38	Alive and well for 15 days. Do. Died of leptospiral infection.* Do. Do. Do.
2	246	4-6-38	14-6-38	
3	218	4-6-38	19-6-38	
4	233	4-6-38	24-6-38	
5	218	4-6-38	4-6-38	
6	247	4-6-38	4-6-38	

* As the animals which received the infective inoculation on 19-6-38 and 24-6-38 died, it was considered unnecessary to inoculate the last two animals of the series.

Laboratories, and recommended for the prevention and cure of leptospiral jaundice in human beings, was used. Young guinea-pigs weighing less than 250 grammes received 0.4 c.cm. each of the anti-sera, obtained from these various sources by intraperitoneal injections. The human and rabbit's sera were without preservatives while the commercial anti-serum was treated with 0.4 per cent tricresol.

Unless otherwise indicated, the infected material consisted of a rich culture of leptospira isolated from the human case referred to above, which had proved extremely virulent to guinea-pigs. The dose amounted to 2 c.cm. in each case. The injections were given into the peritoneum 24 hours after the protective inoculation. An equal number of guinea-pigs of about the same weight, which were treated each with 0.4 c.cm. of normal horse serum before the infective inoculation, served as controls.

All the guinea-pigs serving for control succumbed to leptospiral infection in from four to eight days, the mean being 5.12 days. It will be seen from the foregoing table that the protection conferred on the guinea-pig by the injection of serum of a human case which had recovered from the infection lasted for 25 days, but did not extend beyond 27 days.

From the results of the experiments, as shown in table II, it is evident that the immunity acquired by the injection of immunized rabbit's serum persisted for 41 days but did not continue till the 53rd day.

Inasmuch as the commercial serum was not prepared against the particular strain of leptospira which was employed for testing the potency of the serum, it was expected that the titre of its protective antibodies would be reduced. The infective inoculation was, therefore, given at shorter intervals after the injection of the anti-serum than in the experiments shown in table II. The results in table III show that the immunity acquired by the use of commercial anti-leptospiral serum lasted for 10 days and did not extend beyond 14 days.

Summary and Conclusions

The immunizing value of anti-sera obtained from three different sources was tested. It was found that the immunity acquired by the injection of these sera is a transient condition. As for example, protection conferred on the guinea-pig by the injection of serum of a human case which had suffered from a severe attack of leptospiral jaundice lasted for 25 days but did not extend beyond 27 days, by the immunized-rabbit serum for 41 days but did not continue more than 52 days, and the immunity acquired by the use of 'Wellcome' brand anti-leptospira serum, recommended for the prevention and cure of leptospiral infections in human beings, lasted only 10 days. It thus appears that the administration of anti-serum is not of much practical value as a prophylactic measure, although it can

A METHOD OF FILLING SCREW-CAPPED BOTTLES WITH FLUIDS UNDER STERILE CONDITIONS

By C. L. PASRICHA

MAJOR, I.M.S.

A. J. H. DEMONTE, D.B., I.M.D.

and

S. K. GUPTA, M.B., D.T.M.

(From the Department of Bacteriology and Pathology, School of Tropical Medicine, Calcutta)

DURING the course of a recent experiment in which large quantities of bacteriophage were required, screw-capped bottles were used for its filling and distribution. As these bottles have proved very satisfactory and the method of filling is simple and inexpensive a short description is given below.

Bottles of required size with well-fitting screw caps and of suitable glass are selected. For our purpose we used one-ounce bottles with 'bakelite' screw caps costing Rs. 3-8 a gross. These bottles were available in large quantities in the local market. The cork liner in the screw cap was removed and in its place a rubber washer, cut by means of a hollow punch, was inserted. Washers made from the sheet rubber of a motor cycle inner tube, as described by McCartney (1931) for his blood culture bottles, were found to be satisfactory. Bottles with well-pressed cork-washers of good quality or with liners of thick oil paper can be used.

The bottles with their screw caps loosened a quarter of a turn are arranged mouth downwards in a metal container. This consists of a flat-bottomed metal drum with a flange on which rests a cover on a suitable washer to render the seal air tight. The whole structure resembles a small-sized autoclave, but without the hinged screw and winged nuts. Two removable clamps placed at opposite poles serve to maintain the lid in position and, once the cover has been subjected to atmospheric pressure by the creation of partial vacuum inside the drum, the seal between the filler and the cover remains air tight. In the cover are two openings to which are fitted stop-cocks arranged upright and protected from injury by a removable metal cover. The inside of the filler is heavily tinned or can be nickel or silver plated if desired. It is economical to have the containers of different depths to hold bottles of different sizes, but of

(Continued from previous column)

be usefully employed in inducing resistance to the infection for a short period.

The sera obtained from the first two sources (human and immunized rabbit) were tested against homologous strains. It is therefore expected that the titre of protective antibodies of these sera should be higher than that of the commercial serum, which was apparently prepared against leptospiræ obtained from different sources.

the same circumference, so that one lid can be used for different sized containers. It is convenient to have two removable metal partitions to fit the inside of the container and arranged so that they can be placed at right angles inside the container. This allows the bottles to be arranged more easily and prevents the bottles from falling during their removal.

The container is filled with bottles, the lid placed carefully on the top and is secured in position by the two clamps. The cover is placed on the stop-cocks and the whole apparatus is wrapped in paper and sterilized in an autoclave at 10 lb. pressure for 15 minutes.

For use one of the taps is connected with a vacuum pump through a vacuum reservoir and the other tap is connected with a sterile rubber tubing to a candle for filtration of the fluid. Vacuum is first created in the filler to ensure a perfect seal between the cover and the bottle container and then the stop-cock on the tube connected with the candle is opened and filtration of the required amount of fluid is allowed to take place under a moderate degree of vacuum. When the necessary amount of fluid has passed into the filler, the stop-cock on the inlet connected with the candle is closed and further vacuum is created to exhaust the air in the bottles (usually a vacuum of 30 inches maintained for 5 minutes is sufficient). The connection to the pump is now closed and air, filtered through a cotton-wool filter or through a candle, is slowly admitted into the filler. The bottles are filled and the lid of the filler is removed. The bottles are removed and the screw caps tightened by hand or by that ingenious device of a bored-out rubber bung used by Mackie and McCartney (1934) for opening screw-capped bottles.

The advantages of the use of screw-capped bottles for the filling of fluids under vacuum are

numerous. Where quantities of more than 10 c.cm. are required it is definitely more economical both in actual cost and time to use screw-capped bottles instead of ampoules or rubber-corked bottles as described by Asheshov (1931). Although they have been found particularly useful for filling, storage and distribution of bacteriophage, the screw-capped bottles filled under vacuum can be of great use in the distribution of therapeutic sera such as anti-plague, anti-dysentery, anti-meningococcal and anti-venine sera and of various types of prophylactic vaccines. One of the outstanding advantages of screw-capped bottles is that the screw cap can be removed and part of the contents poured out without any great risk of contamination of the rest of the fluid in the bottle. It has been proved that a bottle containing bacteriophage can be opened to pour out individual dose and closed again without the rest of the contents becoming contaminated. This is due to the fact that the mouth and upper part of the neck of the bottle is covered by the screw cap and remains sterile, whereas in an ordinary corked bottle the mouth is grossly contaminated and the contents soon become spoilt.

Summary

The use of screw-capped bottles for filling and distribution of bacteriophage is described. This method has also been found to be very satisfactory for filling sera and vaccines.

A Mirror of Hospital Practice

A CASE OF TYPHUS FEVER

By S. K. SARKAR, M.B.

Assistant Surgeon, B. N. Railway, Titilagarh,
Sambalpur District

I HAVE been employed as a railway doctor in various parts of the section of the line which passes through jungles from Raipur in the C. P. to Vizagapatam in Madras. This case of typhus fever occurred at Nawapara Road, 60 miles south-east of Raipur. It is the only case of typhus fever I have ever seen and my medical officer who saw this case told me that he had seen only four cases during his 25 years' practice. Sir John Megaw who himself got typhus fever after being bitten by a tick in the Kumaon hills in the U. P. and Col. Stott of the Lucknow Medical College have shown that typhus fever

is not rare in the United Provinces. But typhus fever has been very rarely reported from other parts of India*. Because of this rarity, I am reporting this case, the diagnosis of which was arrived at by a process of exclusion and later confirmed by serum reaction.

History of onset and progress of the case.—On 23rd October, P. S., a station master, aged 47, felt unwell

* We cannot allow this statement to pass without comment. This subject was discussed by us in an editorial in April 1936, when reference was made to a paper by Major J. S. K. Boyd, R.A.M.C., in which he had collected details of 110 cases that had occurred in the army, or in persons associated with the army, during one year only. These cases occurred in many parts of India. The disease is therefore probably widespread in India, but we admit that it is probably not recognized as often as it should be. For this reason we welcome this contribution.—EDITOR, *I. M. G.*

in the morning. At night he had a definite rigor and moderately high temperature (102°F.). Next day he had pain all over the body, worse in the back and thighs. He started vomiting bile and temperature was higher. He was seen by the sectional doctor this day who took a blood slide for malaria parasites and gave him an atabrin musonate injection (0.3 gm.) intramuscularly. Next day, i.e., third day of the disease, his pain was worse, headache very severe and vomiting incessant. He was given another atabrin musonate injection (0.3 gm.). There was no impression on the clinical picture. I was called on 28th October. Temperature was high, headache very bad, vomiting incessant, tongue thickly coated and dry, nervous prostration marked.

As the blood result had not yet arrived and clinically it seemed to be a case of malignant tertian malaria which is common in this district, I suggested another atabrin musonate injection and advised removal to the railway hospital of which I am in charge. On 30th October, 1938, i.e., eighth day of illness, he was admitted into the railway hospital.

30th October.—Temperature (103.4 to 103°F.), vomiting troublesome, headache severe, eyes congested and icteric (might be due to atabrin), nervous prostration very marked, tongue very thickly coated and dry, spleen and liver just palpable, bowels constipated. As the blood result which had arrived by then and therapeutic tests were both negative and the clinical picture was one of continuous temperature with fairly severe toxæmia, I thought now that it was a case of enteric fever. On the same day, i.e., eighth day of illness, serum for Widal and blood slides for malaria, and differential count were sent to the railway bacteriological laboratory at Khargpur.

31st October.—Temperature 101.2 to 101.4°F., vomiting less, other conditions same.

1st November.—Temperature 100.4 to 101.6°F., vomiting stopped, headache very severe, tongue dry, exhaustion extreme. Dark red macular rash noticed in the trunk and upper extremities. Regarded as typhoid rash by me.

2nd November.—Temperature 102.4 to 102.6°F., condition same, rash extensive.

3rd November.—Temperature 102.6 to 101°F., dark red macular rash all over the body, bloated appearance, bronchitis appeared, no urine passed, pulse feeble and rapid, condition worse.

4th November.—Temperature 101.6 to 101.2°F., urine passed, other conditions same. Pathologist's report:—

	1/25	1/50	1/83	1/125	1/250
T	..	—	—	—	—

T (O)	..	—

Blood slide.—No malaria parasites found.

Differential count—

Polymorphonuclears	74 per cent.
Lymphocytes	22 "
Large mononuclears	4 "
Eosinophils	0 "
Abnormal cells	Nil.

Another sample of serum was now sent for Weil-Felix and Widal (twelfth day of the disease).

5th November.—Temperature 102 to 102.2°F., condition same, rash still present.

6th November.—Temperature 99.6 to 102°F., condition a little better, pulse not so feeble, tongue not so dry, rash present.

7th November.—Temperature 100 to 101.2°F., condition better, rash present.

8th November.—Temperature 99 to 101.4°F., condition improving, pulse stronger, tongue moist, rash present.

9th November.—Temperature 100.4 to 100.4°F., condition better, rash present. Pathologist's report:—

	1/25	1/50	1/83	1/125	1/250

XK, O	..	+	—	—	—
X19, O	..	—	—	—	—

Pathologist suggested another sample of serum to be sent later on.

10th November.—Temperature 99 to 100.6°F., condition still more improved, tongue moist, eyes less congested, rash still present.

11th November.—Temperature 98.2 to 99.2°F., touched normal for the first time.

12th November.—Temperature 97.6 to 99°F.

13th November.—Temperature normal throughout the day and kept normal since, rash still present, getting fainter, no desquamation was ever noticed.

20th November, i.e., twenty-eighth day from the onset, serum was again sent for Weil-Felix and Widal. Result is as follows:—

	1/25	1/50	1/83	1/125	1/250
T	..	—	—	—	—
A	..	—	—	—	—
B	..	—	—	—	—
T (O)	—	—
Proteus—					
X2, O	+	+	+	+	+
					(end point not determined).
XK, O	—	—	—	—	—
X19, O	—	—	—	—	—

Conclusion.—But for the serum tests (Widal and Weil-Felix), this case would certainly not have been diagnosed by me.

The source of infection could not be ascertained. The patient is emphatic that he was never bitten by a tick, a flea or a mite. There has been no other case of typhus in that house or locality. Under the circumstances I conclude that this was a case of non-epidemic tropical typhus of unknown or uncertain vector (Megaw's classification).

Treatment was symptomatic. Sulphonamide (B. & W. Co.) was tried empirically for four days (6 tabloids a day for first two days and 3 tabloids a day for next two days) with no apparent effect.

Diet was butter-milk and orange juice throughout (two-hourly feeds, alternately).

My thanks are due to my chief, Dr. W. D. Speedy, for permission to publish this case, to my medical officer, Dr. M. N. Sarkar, who saw the case and confirmed my clinical diagnosis, to Dr. Mandal, Malaria Inspector, Ambodala, who examined the blood slide and to Dr. M. Sen-Gupta, Pathologist to the B. N. Railway, who carried out the various tests and thereby confirmed the diagnosis of typhus fever.

Indian Medical Gazette

APRIL

THE ANTI-TUBERCULOSIS MOVEMENT AND SOCIAL SERVICE

THE King-Emperor's Anti-Tuberculosis Fund has been closed; the total of 76 lakhs is a little below the figure that Her Excellency the Marchioness of Linlithgow hoped to raise, but, in times that are far from affluent, it is a very notable achievement to have raised so large a sum. Sufferers from tuberculosis, present and future, and their friends and relatives, will owe an eternal debt of gratitude to Her Excellency for planning so skilfully and carrying through so energetically 'the first successful engagement in a great campaign'. That Her Excellency has had the support of the spokesmen of all castes and creeds, of people of all shades of political opinion, and of the whole press in this vast and heterogeneous country, is greatly to the credit of both the appellant and those to whom she appealed.

The arrangements being made under the aegis of the Fund imply that for the first time in Indian experience special measures for combating tuberculosis in a methodical and expert manner are being taken, and permanent committees are being set up. Preparations are now well advanced for the actual task of relieving the sufferers from this disease and opening the real fight for its eradication', says Her Excellency in her statement on the closing of the Fund.

It will be a great mistake if those interested in this movement imagine that they may now relax their efforts; on the contrary, 'they should again advance and engage the enemy, an enemy far more difficult to subdue than any army of disciplined troops, an enemy which fights by stealth and lurks in every corner of every home. It is only by means of unremitting vigilance that success will finally be achieved, and this enemy of mankind overcome', to quote from the same statement.

When the appeal was launched it was suggested that there would be a central body and provincial—and possibly state—organizations. The central body has now been registered as the Tuberculosis Association of India. Many provincial tuberculosis associations already exist, and other provinces and many of the states have agreed to form their own associations, all of which will in due course be affiliated to the central association.

Elsewhere in this number will be found a statement regarding the policy of the central association. The central association will not control the provincial associations in any way; it will act only in an advisory capacity and as

a co-ordinating agency. It will establish a statistical and information bureau and will standardize methods so that data and results obtained in different provinces will be comparable. Other co-ordinating activities will include promoting conferences, training workers, and possibly publishing an all-India tuberculosis journal. Research, and education of the public by different forms of propaganda, will fall within its scope.

The duties of the provincial organizations will be numerous and varied, and will depend largely on the special local conditions, but with a total of probably two million cases of tuberculosis in India it is obvious that under present economic conditions sanatorium accommodation cannot be provided for even one per cent of sufferers, and that the tuberculosis dispensary will be the mainstay of the campaign against this disease. It has often been suggested that at the tuberculosis dispensary the patient can get little more than the diagnosis of his disease and advice on the form of treatment most suited to his case. This of course is a pessimistic point of view, as it is possible to do much more than this under dispensary conditions, *e.g.*, to mention one point only, the initiation and maintenance of collapse therapy. But, nevertheless, it is true that unaided the tuberculosis dispensary would put up a poor fight against this disease and the success of a dispensary in any district will depend largely on the amount of support it obtains from the social service organizations in the locality.

A statement on the subject of social service and tuberculosis which has recently been issued by the executive of the King George V Anti-Tuberculosis Fund is reproduced elsewhere in this number. This should be read carefully by all interested in the subject, as it presents in a very clear and concise form the scope and opportunities for social service in connection with the tuberculosis problem. The responsibility for the organization of the social service should not rest in any way with the dispensary staff, but the formation of a local 'care committee' should be undertaken by responsible residents in the locality. The work initiated by this committee should of course be on a voluntary basis, but funds will be necessary and and it should be emphasized that these should be entirely separate from the funds of the dispensary. There will be ample opportunities for those who cannot afford to subscribe to the funds, but are prepared to devote some of their time to the work undertaken by this committee.

As the value of the dispensary will depend largely on the amount of local support and co-operation that it obtains, it is obvious that dispensaries should be placed only in such places as are likely to give this support, and, as the executive of provincial tuberculosis associations will be largely influenced in this matter by the state of the existing social services in any locality,

A STUDY OF THE DIET OF THE BENGALI HINDUS AND THEIR NUTRITION

By DURGA DAS MITRA, M.B., D.P.H., M.Sc.
(From the Department of Biochemistry and Nutrition, All-India Institute of Hygiene and Public Health, Calcutta)

THIS study comprised the following numbers of families at the stated places :—

Place	Number of families	Number of persons	Number of consumption units
Dinajpore ..	40	204	168.2
Barasat ..	10	79	58.8
Calcutta ..	5	48	38.5

The Calcutta families were of the better type middle-class, including officers and professional people, earning about Rs. 200 to Rs. 500 a month.

Dinajpore and Barasat families belonged to the agricultural class. They worked on the land themselves and often employed additional labour as well. Practically all of them were dependent to a large extent on the land to supply their needs. Existence appeared to be rather hand to mouth, and little money was handled. At Barasat, a certain amount of barter existed, fish, etc., being exchanged for soil products. From the local conditions it appeared that the families under observation at Dinajpore were poorer than those at Barasat, and this supposition was later on verified by the calculated analytical figures of their respective diets. It seemed however that more could have been made of the ground, had they possessed the will and energy to work it, and worked harder.

Diet survey

The survey was carried out by a house-to-house visit and covered a period of three weeks in Dinajpore, and a week each in Barasat and

		Vitamin C, mg. ..	45	86	133	30-50	95

Calcutta. The analysis of the diets covers the following; total protein, animal protein, total fat, animal fat, carbohydrate, total calories, per cent calories from cereals, total minerals, calcium, phosphorus, Ca:P ratio, iron, vitamin A, carotene, vitamin B₁, flavin, vitamin B₆ (antidermatitis), and vitamin C.

The food values were taken largely from the *Health Bulletin No. 23* (Aykroyd, 1937) and from figures obtained from the laboratory.

Discussion of diets

The family coefficients, as given in the *Health Bulletin*, have been employed for working out the consumption units (henceforth c.u.).

The following are the calorie consumptions per c.u. per day :—

Groups	Calories
Dinajpore ..	2,742
Barasat ..	2,743
Calcutta ..	2,787

The League of Nations (1936) puts forward a figure of 2,400 calories net *plus* 75 for each hour of moderate work; assuming that they do an eight-hour day, this would mean a total requirement of 3,000 calories net. The British Medical Association (1933) comments that 3,400 calories, in the food as purchased, is a safe figure for the daily requirement; this should assure 3,000 available calories, allowing for wastage in preparation and digestion. The *Health Bulletin* suggests a total daily intake for the average Indian of 2,600 calories.

The similarity between the Dinajpore and Barasat figures is striking, and their difference from the Calcutta figure is not marked. But the calorie needs of the agricultural manual labourers are much more than the Calcutta well-to-do people, and it may be assumed that they actually consume less than they should.

Protein

The consumption of protein ranges from 70.6 g. (Dinajpore), 78.4 g. (Barasat) to 94.0 g. (Calcutta) per c.u. The percentage derived from animal sources likewise shows a similar trend, *viz.* 5.4 per cent (Dinajpore), 10.8 per cent (Barasat), and 47.7 per cent (Calcutta). The well-to-do in Calcutta obviously by choice have a protein consumption which is about quantitatively and qualitatively on a par with European standards, while the agriculturists are at a definitely low level in both those respects.

Fat

The consumption of fat ranges from 14.0 g. (Dinajpore), 19.7 g. (Barasat) to 86.5 g. (Calcutta) per c.u. The percentage derived from animal sources likewise shows a similar trend, *viz.* 4.9 per cent (Dinajpore), 14.3 per cent (Barasat) and 46.9 per cent (Calcutta). It is interesting to note that these percentages run more or less parallel to those of protein,

though with an improvement in the economic status, the absolute increase in the fat intake is much greater than that in the protein. The Calcutta families consumed six times as much fat but even less than one-and-half times as much protein, as the Dinajpore agriculturists. A similar observation has been made in Europe by Catheart and Murray (1932), where an increase in the food budget was associated with a larger fat consumption, often with little or no change in the protein level. The problem of the fat requirements is as yet an unsolved and somewhat neglected problem, but, from the standard of 45-60 g. given in the *Health Bulletin*, it appears that the agriculturists consume very little indeed !

Carbohydrate

As was to be expected, the agriculturists consume more carbohydrate, chiefly derived from the cheap cereals, than the Calcutta families; in fact, they derive about 80 to 90 per cent of their total calories from cereals, whereas the Calcutta families derive only 48 per cent.

TABLE II

Showing percentage distribution of calories in protein, fat and carbohydrate

Place	Dinajpore	Barasat	Calcutta	British Medical Association recommendation (1933)
First class protein	0.6	1.2	6.5	6
Second class protein	9.8	10.2	7.1	6
Fat ..	4.6	6.5	28.3	27
Carbohydrate ..	85.0	82.0	58.0	61

The table vividly shows the adequate distribution of calories in the proximate principles in the Calcutta group according to the British Medical Association standard, and the inadequate distribution among the other groups.

Minerals

The consumption of total minerals, calcium, and iron gradually increases from the Dinajpore group to the Calcutta group, while the phosphorus figure does not show much variation, with the result that the Ca:P ratio gradually increases, *e.g.*, 1:10.2 (Dinajpore), 1:4.6 (Barasat), and 1:2.6 (Calcutta). Sherman (1937) observes that 'during rapid growth and calcification, it is well that the food as a whole should have a Ca:P ratio somewhere between 1 and 2'. Only the Calcutta diet approaches this standard.

The calcium consumption in Calcutta families satisfies the recognized standard, though the agriculturists fall below it. The phosphorus and iron consumptions are up to the mark in all, the former mainly coming from the cereals and the latter from the green vegetables in the case of the poor villagers.

Vitamins

Carotene in the present analysis is expressed in terms of its corresponding vitamin-A equivalent and it is found from the table that the vitamin A (including carotene), vitamin B₁, and

brought out by calculating the increase in body-weight in relation to the protein consumption. The following table (IV) shows, between the age groups 7 and 12, the average increase in body-weight per annum in kilogrammes, and the

TABLE III

Showing height, weight and dynamometer grip of the Dinajpore, Barasat and Calcutta boys

Age group	HEIGHT			WEIGHT			GRIP		
	Dinajpore	Barasat	Calcutta	Dinajpore	Barasat	Calcutta	Dinajpore	Barasat	Calcutta
7	45.0	45.8	48.1	41.2	40.8	47.7	13.3	14.7	14.0
8	47.6	47.2	48.5	48.1	43.9	50.2	17.8	16.6	19.9
9	49.6	49.8	51.3	51.1	50.9	56.2	19.9	19.9	20.9
10	50.9	51.7	52.4	54.8	54.7	58.3	21.8	22.8	21.6
11	51.4	53.1	53.8	59.5	59.8	63.4	24.8	25.7	24.8
12	54.0	54.7	56.5	64.2	63.1	75.0	25.8	27.3	28.4

vitamin C satisfy the standards in all cases, except a deficiency in vitamin A (including carotene) in the Dinajpore group, where further a dearth of fat in the diet may be responsible for the carotene being not all absorbed. The deficiency in carotene in Dinajpore however can be easily rectified by taking more of the green leafy vegetables, *e.g.*, amaranth leaves. In villages many edible leafy vegetables grow by the sunny wayside, and the villagers have only to pluck them in order to get them, as is done in Barasat.

Growth of the children

Children for proper growth require proportionately more protein (specially animal protein) and more calcium, phosphorus and total calories than adults.

The deficiencies in the important food principles, specially among the agricultural class boys, produce in corresponding age groups, less growth in height, weight and the power of grip as compared with the better-off class boys

increase in weight per annum per kilogrammes body-weight per gramme of protein consumed per day.

TABLE IV

	Average rate of growth per annum, kg.	Average rate of growth per g. protein consumed per kg. body-weight per day
Dinajpore ..	2.10	1.11
Barasat ..	2.05	0.93
Calcutta ..	2.46	1.07

It is to be noted that there is not much difference between the rates of growth per gramme of protein consumed in the three groups, and, if anything at all, a slightly higher rate at Dinajpore would appear to indicate that in this group the assimilation and utilization of protein and/or food is somewhat better than in the other

CHART 1

Height—Age.

CHART 2

Weight—Age.

CHART 3

Dynamometer grip—Age.

(table III, Charts 1 to 3). A similar observation was made in a previous survey (Wilson, Ahmad and Mitra, 1937).

A significant feature which probably illustrates physiological economy in nutrition is

groups with a larger food intake, though it seems possible that an insufficiency of building materials has at an earlier age kept back the Dinajpore group to the Calcutta group by a year or two.

Symptoms of deficiency and other diseases

The incidence of caries showed no correlation with diet (21.1 per cent at Dinajpore; 26.1 per cent at Calcutta). The incidence of enlarged tonsils, if anything at all, appeared to show a negative correlation with the poverty of the diet. Among Dinajpore boys it was 11.3 per cent while at Calcutta it was 44.6 per cent. The open, comparatively cleaner air and the sunshine, in which the village boys play and work, may be responsible for the comparatively less incidence of caries and enlarged tonsils

TABLE VI
A C H index figures

Locality	Total number examined	A C H INDEX SELECTION	
		Number	Per cent
Dinajpore ..	318	146	45.9
Barasat ..	198	67	33.8
Calcutta ..	331	54	16.3

TABLE V

Showing incidence of different clinical conditions observed among Dinajpore, Barasat and Calcutta boys. Number of cases and percentage

Locality	Total number examined	Angular stomatitis	Phrynodermia	Xerophthalmia	Bitot's spots	Caries	Mal-occlusion of the teeth	Enlarged tonsils
Dinajpore	539	31 (6.3%)	3 (0.5%)	11 (2.0%)	5 (1.0%)	114 (21.1%)	46 (8.5%)	61 (11.3%)
Barasat ..	294	82 (27.9%)	44 (14.9%)	85 (28.9%)
Calcutta ..	298	48 out of 184 cases examined for caries (26.1%)	24 (8.0%)	133 (44.6%)

among them. Besides, the higher incidence of caries among the well-to-do may be associated with the consumption of sweetmeats.

The correlation between the incidence of mal-occlusion of teeth and the economic status which was observed in a previous survey (Wilson and Mitra, 1938), and Nicholls (1936) in Ceylon, was not however observed to exist in a great degree in the present case, 8.5 per cent at Dinajpore and 8.0 per cent at Calcutta.

Definite cases of angular stomatitis (6.3 per cent) and phrynodermia (0.5 per cent) were observed amongst Dinajpore boys, while only a few doubtful cases at Barasat or Calcutta. The skin of the Dinajpore children was dry and rough in many cases both in appearance and touch. This dryness of the skin and the incidence of phrynodermia may be associated with their low fat and vitamin-A (including carotene) intake.

Also the incidence of xerophthalmia (2 per cent) and Bitot's spots (1 per cent) among Dinajpore boys is significant as the vitamin-A (including carotene) consumption is only about 1/4th of the recognized standards, while not a single definite case was noticed at Barasat or Calcutta survey. Practically all the cases of Bitot's spots gave also a history of night blindness.

A C H index

The selection is correlated with the economic status, being highest in Dinajpore, and lowest in Calcutta. But in a previous survey (Wilson *et al.*, 1937), the index appeared not to be applicable to different economic classes at Calcutta.

Summary

A diet and physique survey was carried out among several agricultural families at Dinajpore (North Bengal) and Barasat (24-Parganas) and some well-to-do families at Calcutta.

The diet of the well-to-do appears to approximate in most respects to the European standards. The diet of the agriculturists is deficient in animal protein, total and animal fat, total calories, calcium and vitamin A.

Better growth in physique is definitely found to be associated with better food.

Association between caries and enlarged tonsils and diet is not apparent, though phrynodermia appears to depend on deficiency of vitamin A and fat, either singly or both, and Bitot's spots is definitely associated with vitamin-A deficiency.

THE DRUG INDUSTRY IN INDIA AND ITS DIFFICULTIES*

By R. N. CHOPRA, C.I.E., M.A., M.D., Sc.D. (Cantab.),
F.R.C.P. (Lond.)

BREVET-COLONEL, I.M.S.

*Honorary Physician to the King,
Director, School of Tropical Medicine, Calcutta*

It is a matter of satisfaction to me, who has been associated with the drug industry in India from the scientific side for the past two decades, that appreciable progress has been made during recent years. India abounds in medicinal plants and the existence of many possibilities of drug manufacture in this country emerges clearly from the fact that foreign manufacturers draw their supplies of much of the raw materials from this country. The root cause of the traffic in adulterated drugs was traced by the Drugs Enquiry Committee, on ultimate analysis, to the demand for cheap medicines in this vast continent. Some unscrupulous manufacturers in India and abroad have not been slow to exploit this and, in the absence of restrictive laws, a certain class of manufacturers and dealers has been successfully flooding the market with an inferior grade of products. The true remedy for this state of affairs lies in the organization of the drug industry in this country, which would be able to satisfy the conditions which might be prescribed by properly considered drug-control legislation, and to put on the market standard goods which would suit the purchasing capacity of the people whose economic condition is low. The question of stimulating the manufacture of drugs in India and that of ensuring the supply of pure medicine of proper standard, at prices commensurate with the means of the people, are inter-dependent. A perusal of the sea-borne trade statistics of British India shows that India imports medicinal drugs and preparations, pharmacopœial and otherwise, to the extent of nearly two crores of rupees every year while the value of drugs exported is comparatively very small. This means that while much raw material is going out of the country, considerable quantities of refined preparations are coming in. Many of the imported drugs are standardized pharmacopœial preparations such as galenicals and purified alkaloids, in many cases manufactured from the crude drugs which have been exported.

Thanks to the pioneer efforts of men like Sir P. C. Roy and others, manufacture of medicinal drugs in this country has progressed during recent years. Twenty years ago only a few firms manufacturing drugs existed in India, now there are quite a large number of reliable drug manufacturers in different parts of the country.

Calcutta alone can boast of at least half a dozen large factories, if not more, which would be an asset to any country. Formerly, a considerable proportion of this business consisted in diluting extracts of drugs imported from Europe and America; but now most of the drugs are manufactured in this country. Few only of the drugs indigenous to India were used in the manufacture of galenicals; but now most of the firms use indigenous raw materials. Mineral acids, inorganic and organic metallic compounds, alkaloids, glucosides and essential oils, proprietary medicines and medicinal specialities similar to those imported, are being manufactured. Even biological products such as gland extracts, sera and vaccines, etc., of good quality are being prepared, though on a very small scale considering the requirements of this vast country.

While a lot has been done, much still remains to be accomplished and there is considerable room for expansion in many directions. This is evident from the figures of imported medicinal preparations to which I have just referred and which include, not only special preparations but considerable quantities of galenicals, powders and extracts, about the manufacture of which there can be no possible difficulty. I have been studying this problem for many years and the reason for the existing state of affairs to my mind is that the indigenous manufacturers of drugs have not yet gained the full confidence of the medical profession in this country. Many practitioners insist on using even the ordinary galenicals prepared by reliable firms abroad, which so to say have a hall mark of quality and strength, in preference to indigenous articles however good they may be. The presence in the market, of medicinal preparations of an inferior quality, manufactured by firms of doubtful integrity side by side with good ones, has made them suspicious, and rightly so. While there is no doubt that manufacturers of inferior drugs exist both in India and abroad, there is one important thing which is not fully appreciated by the profession here and that is the effect of climatic conditions and storage, such as are met with in this country, on the medicinal preparations, and about which very little information is available at present. It must be remembered that these conditions affect both the preparations which are manufactured in India and abroad, however good they may be to start with. The effect of climate and storage is no doubt much more marked on some preparations than on others, but it has been conclusively shown that the potency of a number of the important preparations is materially altered in such a way as to be of serious significance to those who use them. I have watched many preparations of ergot and digitalis which had been properly standardized and were of the required strength when they left the factory, but within a few months they lost a considerable amount of their potency and became of below standard. This has naturally been a source of

*Being an address delivered at the opening of the Exhibition in connection with the Campbell Medical School Annual Reunion on the 14th January, 1939.

considerable anxiety to the manufacturers, both in India and abroad, as these factors apply equally to imported and indigenous preparations made by the best of firms. The fault does not lie with the makers but is attributable to factors yet imperfectly understood. One of the duties of the Drug Control Laboratories laid down by the Drugs Enquiry Committee is to work out the factors responsible for deterioration of medicinal preparations by climate and storage factors, and this is now being done by the Biochemical Standardization Laboratory which is the nucleus of the Drug Control Laboratory as visualized by the Drugs Enquiry Committee.

While such factors undoubtedly do exist, there is no denying the fact that on account of want of proper organization and lack of requisite knowledge of the intricacies of the problem of drug manufacture, the quality of indigenous products in some cases is not in keeping with the high standard that is expected. It should be realized that for the proper development of this industry the guidance by expert chemists, botanists, pharmacologists and bacteriologists is essential. Unless the development of this industry proceeds hand in hand with carefully planned research work, the progress will be extremely slow. In India unfortunately the rôle of scientific research in connection with the development of the drug industry is not fully appreciated and expenditure in this connection is often considered unnecessary and unjustifiable. This is in marked contrast to the attitude taken up by manufacturers and industrialists in

the Western countries. Large sums are set apart there for scientific research which is considered to be the pivot on which progress of the industry depends. A visit to the research laboratories of reliable firms of drug manufacturers such as Burroughs Wellcome in England, Bayer in Germany, Parke Davis in America, etc., will convince anyone of the supreme importance which is attached to this side and the part which activity in this direction plays in their success. Without the development of the research side it will be futile to expect any material progress.

Any scheme of drug manufacture in India, if it is going to be successful, should have the following objects in view:—(1) To supply the masses of India with medicinal preparations commensurate with their means. (2) To fight against preparations of impure quality and defective strength getting into the market. (3) All the basic material for manufacture of different preparations should be produced in the country and manufactured into a suitable form for administration and not imported from abroad, as is being done by many firms at the present time. (4) The importance of associating strong research units with the manufacturing organizations has not been sufficiently appreciated. Unless this is done the progress is bound to be slow and it will not be easy to improve the standard of preparations manufactured. (5) If 'quality and strength' is made the motto of the manufacturers, success will be assured and difficulties which undoubtedly exist will be overcome.

Medical News

SOCIAL SERVICE AND TUBERCULOSIS

*A statement issued by the King George V
Anti-Tuberculosis Fund Executive*

PROPAGANDA connected with the successful King-Emperor's Appeal for funds has not only instructed the people of India as to the vastness of its tuberculosis problem, but it has also carried with it the message of hope that the disease can be prevented and that a great many of those who do suffer from the disease can be cured if treated properly. It has been estimated that not less than two million people are suffering from active tuberculosis in the whole of India. This number is so huge that for many years to come modern institutional treatment can be available for but a small proportion of the sufferers, and for the great majority of them treatment must be provided in their homes.

This is one of the reasons why those responsible for the technical planning of the tuberculosis effort in India have put the establishment of tuberculosis clinics, in suitable centres, throughout the country, in the forefront of the campaign against the disease. These clinics will be centres where those suffering from the disease, and private practitioners treating tuberculous patients can obtain expert advice in order to make home treatment as efficient as possible, under the circumstances.

The character of the tuberculosis clinic will largely depend on the needs of the local community and on the funds available. The minimum requirement will be a place for the reception and examination of patients,

and for treatment which in some cases may have to be given in the clinic; there must be a tuberculosis doctor and one or more specially trained tuberculosis health visitors attached to the clinic. But, if the work of this technical staff is to be of the greatest possible value, it must be supplemented and supported by an organization for social service, namely, a 'care and after-care committee' of voluntary workers.

2. To a great extent tuberculosis social service in India is an 'unblazed trail', and the committee of each clinic will have to embark upon its own explorations of discovery, guided by the work that has been and is still being done by pioneers. There must be few parts of India, however, where there is not a great sympathy for sufferers from the disease, at least in the many families who have had personal experience of tuberculosis among their own relatives, and from among these sympathisers there will naturally be those who will be ready to help in voluntary service. To enlist these people in a 'help or care committee' should be one of the earliest thoughts of those responsible for the work of a clinic. This committee should, of course, include the tuberculosis doctor, and, possibly, one or more of the tuberculosis health workers connected with the clinic, but the Secretary should not be one of the technical staff. It is essential that in forming the committee there should be chosen as members not only those who can give their time and energy in personal service to tuberculosis patients and their families, but also those who can influence the public, create confidence and obtain support, on account of their own keenness, interest and sympathy. The whole

of the work of this committee is a contribution of social service in connection with tuberculosis.

3. Social service as applied to the tuberculosis patient is not easy to define, specially as it is so varied in its expression, but in general it can be summed up as 'a study of the social condition of the patient with a view to bringing the knowledge gained therefrom to the help of the patient, both to hasten and safeguard his recovery and to prevent the spread of the disease to others'.

The work of the 'care committee' will be concerned with two groups of patients, although the line between these two groups is not very sharp. There will be many patients too poor to pay for their own private doctor or for their treatment and who, therefore, will have to be helped from the clinic. The clinic doctor and nurse will have to visit these patients in their own homes, specially when they are not able to come to the clinic. Assistance from members of the care committee will be invaluable to the doctor and nurse, in caring for the social needs of these patients, without which care much of the medical help would be wasted or useless.

The other group will be those patients who can pay for their medical aid or even for their own doctor, and it is important to enlist the aid of the private medical practitioners in such cases. The clinic is not meant to compete with the private practitioners, but is there to help them in every way possible, by giving free, expert advice which can best be provided if the private practitioner keeps the clinic informed of the progress of the patients treated by him in their own homes. With these patients the work of the care committee is different; it should promote the co-operation of the local medical practitioners with the clinic, with a view to the control and prevention of tuberculosis in the whole area. This co-operation is a matter of supreme importance, if the tuberculosis scheme is to be successful. The care committee can also provide for many of these patients various forms of service or help which they would be glad to avail themselves of, and which might be difficult to obtain otherwise, in spite of their ability to pay for their doctor and their treatment. All the work of the care committee for this class of patients must be done with great tact and with the full knowledge and co-operation of the private practitioner.

For some patients, who are too poor to pay for their own doctor, the care committee may, under certain circumstances, such as distance from the clinic, arrange for treatment in their homes by private medical practitioners, paying such doctors a small fee for their services.

The care committee can also strive to bring into contact with the clinic or private medical practitioners, any patients who have not yet come under medical advice, because such contact is necessary if tuberculosis is to be stamped out.

4. For the carrying out of the work of the care committee, it must have sufficient financial support. But money for social service should never be provided from the general funds of the clinic intended for the staff and medical work, and an important function of the care committee will be to raise subscriptions from the public for its particular work. Such support will readily be given if there is evidence of useful work by the committee, as part of the Clinic's activities, in fighting the disease and in making it safer to live in that locality. The care committee will maintain its own fund with its own honorary treasurer, who, like the secretary, should not be one of the technical staff of the clinic. While it is not possible to define all the uses to which the funds of the committee should legitimately be put, the following may be suggested:—

(i) Giving relief to poor patients, after the committee has, by personal investigation, found such relief is necessary.

(ii) Payment for transport of patients to clinic, hospital or sanatorium.

(iii) Provision, in special cases, of medicines, and medical necessities, which though considered necessary

by the doctor, cannot, because of their cost, be provided by the clinic or the patient.

(iv) Payment of x-ray charges for poor patients, when the clinic has not its own x-ray, but can get such work done by a local hospital on payment.

(v) Provision of extra nourishment on the recommendation of the clinic doctor.

(vi) Provision of other place for treatment of a patient for whom treatment is impracticable in his own home, due to unhygienic or overcrowded conditions, and for whom institutional treatment is impossible to obtain.

(vii) Provision of other place of treatment, as a preventive measure, for a patient who is a dangerous source of infection, if he is left in his own surroundings.

(viii) Provision of aid for families whose natural supporter is sick, whether in the home or in hospital or sanatorium.

(ix) Arranging for the care and, if necessary, boarding out of children, if the mother is sick.

In addition to forms of service requiring money, there are many forms of service which the members of the committee may undertake, without expense, such as personal visits of the sick, providing literature for those who can read, and small personal services, too many to describe in detail.

5. The social service of care committees so far mentioned has been to patients while they are actually suffering from the disease. There is, however, one other not less important function of the care committee, and that is, the care for those who have been under treatment and have been considered fit to return to a more or less normal life. This function is usually styled the after-care of the patients.

The committee should make it their concern to help such ex-patients, specially during the first dangerous years after their illness, when there is, in many cases, the risk of a set-back, which would undo all the benefit of their treatment. The after-care of such patients would include the finding of suitable employment, according to medical advice. The employment may be their old occupation, either whole or part-time, or it may be a new one more suitable to the health and strength of the ex-patient. In many cases it will mean enlisting the sympathy of the employer, and if the ex-patient cannot work whole-time, to get the employer to give part-time or light work, and so to make this his contribution of social service to the tuberculosis scheme.

For some ex-patients, the committee may be able to start them in a new way of making their living independently, and if necessary, provide the training for the new occupation, such as small cottage industries, bee-keeping, or petty trades.

The above are some of the ways in which the care committee can help the fight against tuberculosis, either by their own efforts or by the aid of collected funds. With experience, their scope and usefulness will undoubtedly grow.

In conclusion, it must be emphasized that the care committees should not work as isolated branches of the tuberculosis scheme, but always in close co-operation with the clinic and private practitioners co-operating with the clinic. Only then will the social service they render play the fullest part in the combating of tuberculosis in their midst and so be an effective help in the whole campaign in India.

THE TUBERCULOSIS ASSOCIATION OF INDIA

Policy of Central Association

ONE of the first duties of the new Central Association will be to decide, in general outline, the methods which it will use to carry out its task of dealing with the All-India tuberculosis problem. While the constitution for the Centre has been liberally designed in order that every use may be made of any recognized activity able to influence the prevention or cure of the disease, the active campaign, i.e., the creation of hospitals or clinics, and carrying out of preventive measures, must primarily be the responsibility of the provincial state association. The deciding factor in

formulating its policy will therefore be the relationship of the provincial state associations which are independent bodies, governed by constitutions of their own. The Centre can exercise no controlling influence over the affiliated associations, but should organize itself so as to be in a position to offer expert advice, and to become a co-ordinating agency, e.g., in standardizing methods, in promoting consultations or conferences, in training workers and in educating the public by different forms of propaganda. The promotion of research will be another important function, while its work will be assisted by the formation of an information and statistical bureau and by the publication of an All-India tuberculosis journal. It is, therefore, evident that the Central Association has a most important place in the whole tuberculosis effort, especially as it is hoped that the provincial state associations will co-operate in order to form a united, co-ordinated and efficient general campaign against the disease.

The main work of the Centre will be controlled by a general committee, delegating work to different sub-committees, of which the most important will be a technical or medical sub-committee. It is assumed that similar organizations will be created by all the larger affiliated associations, at least.

The Technical Adviser. It will be necessary to make this important appointment at a very early stage. At the present time, there are comparatively few experienced expert workers in India, but this post must be filled by a medical officer whose experience and standing is such that his advice will carry weight and influence with provincial and other associations, to which his services will always be available.

It is desirable to consider the various functions of the Centre as indicated above in greater detail.

1. Advisory functions

The advisory functions of the central committee will be many. It must be prepared to offer general advice with regard to the tuberculosis policy and detailed advice with regard to location, construction, equipment, staffing and functions of tuberculosis clinics and other tuberculosis institutions. Advice should also be available with regard to propaganda, education or training of tuberculosis doctors and other tuberculosis workers, research, care and after-care organization, the place of private practitioners in local schemes, etc.

2. Co-ordinating functions

Duplication of effort should be avoided; propaganda material, for instance, produced either by the central or provincial association should be made available throughout India by the centre. Methods of training, specialized medical education, standardization of buildings, forms and hospital organization should be communicated. A valuable method of assistance in these matters and of bringing workers in touch with new methods will be by

(a) promoting conferences of tuberculosis workers,

(b) propaganda; by producing special material for distribution throughout India, the Centre will be carrying on an activity which has all along been used with effect by the King George Thanksgiving (Anti-Tuberculosis) Fund. In this matter the continued co-operation of the Red Cross Society will be valuable.

(c) *Training and education.*—This has been another successful activity of the King George Thanksgiving (Anti-Tuberculosis) Fund. Until each province has developed its own training centres, the central committee might arrange courses of training of shorter or longer duration, using experts from different parts of India, with a view to increasing the number of tuberculosis workers for the many institutions which will be required in the near future. Delhi itself would be an excellent centre at which doctors might receive special training. In addition, the institution of a special course and the granting of a diploma for tuberculosis will be worth investigating. The Delhi hospitals and the special expert on the staff at the centre could co-operate to make such a training successful.

(d) *Research.*—Special investigation of tuberculosis problems is carried out at present by the I. R. F. A., who will no doubt continue to promote and assist such activities in so far as their finances permit. Not only will the central committee through its medical members and its expert adviser keep in touch with such work, but it will assist in communicating the results obtained to tuberculosis workers throughout India. The expert should be encouraged to carry out researches himself and the centre should also be in a position to arrange for financing such work.

(e) *Information and statistical bureau.*—The central committee should also arrange an information and statistical bureau, which will collect, analyze and distribute information on all tuberculosis matters not only for affiliated associations but for institutions, the medical profession, the press and the general public. Such a bureau will require a good library with proper arrangements for supplying information on any matters connected with tuberculosis.

(f) *Journals.*—Part of the co-ordinating work of the central committee will be publication of journals, such as an Association Journal, dealing with various activities in India and elsewhere and containing general propaganda material; possibly later on a medical journal for tuberculosis in India might be practicable.

Special tuberculosis institutions.—As noted above, the creation and maintenance of sanatoria, hospitals and clinics devoted to the treatment of tuberculosis are matters which will be dealt with by provincial state organizations. Although the centre by its constitution has the power to undertake such responsibilities it will not do so immediately. It may however be necessary later to organize and support model institutions in Delhi in connection with its educational and research responsibilities. These should be designed to meet the necessary special requirements.

FINDINGS IN NUTRITION SURVEY

THE richer you are the more fat you eat. Investigations under a scheme approved by the Nutrition Advisory Committee of the Indian Research Fund Association have shown that a special feature of the Indian diet is a marked increase in the consumption of fat with the rise in economic scale.

Four types of communities in different areas were selected for diet and clinical surveys, namely, industrial workers in Assam (the coolie class), the middle class agriculturists in Bengal, the well-to-do Calcutta households and a mixed middle class community in Ferozepore, Punjab.

The diet of the Assam coolies was found to be poor in total calories, in total proteins, in fat, in calcium, in vitamin A and in carotene, also to a lesser degree in vitamin C and in iron. Most of the families took no milk. Conditions were somewhat better among the middle class agricultural group though the fat and the animal protein consumption was low. The diet of well-to-do people in Calcutta was almost as good as that recommended in the European standards.

Children examined

Together with the diet surveys, the children were examined for height, weight and deficiency diseases. The heights and weights of the Assam children were much below those of the well-to-do group in Calcutta and those of the rural children were midway.

While the absolute gain in weight per year was somewhat greater in the Calcutta children, growth expressed as a percentage increase in body weight per year was actually greater in the labour class in Assam. In spite of the poor diet the growth impulse appeared to be as good amongst this class as among the well-to-do. They had also probably a greater proportion of muscle tissue per unit of body weight than the better-off group.

These surveys show that Assam coolies live on a diet which is inadequate qualitatively and probably also quantitatively. To a lesser extent it is also true of the agricultural community in Barasat, Bengal, yet the inherent vitality, as judged by the percentage rate

of growth and grip per lb. body weight, appeared to be good.

Definite signs of vitamin-A deficiency in the diet were seen only in Assam, the rural area in Bengal and Calcutta being exempt from them. Mal-occlusion of teeth, of which the cause is obscure, was most common among the Assam children (23.2 per cent) and least in Calcutta (8.0 per cent). On the other hand the incidence of enlarged tonsils was greater among the well-to-do (42.3 per cent) and least among the coolies (12.8 per cent). Conditions of malnutrition were present amongst 38.7 per cent of boys in Assam and amongst 33.8 per cent in rural Bengal, and 16.3 per cent in Calcutta. These figures, however, fell with the rise in economic status.

The average number of children alive per family was 1.8 in Assam, 3.5 in rural Bengal, and 4.2 in Calcutta. In none of the groups were children sent away elsewhere; indeed in Assam they obtained employment in the industry from the age of seven.

Better diet in Punjab

The families surveyed in Ferozepore, Punjab, included Hindus, Muslims, Sikhs of the artisan class, and a small group of sweepers. The diet of this mixed group was almost as good as that of the well-to-do people in Calcutta in calories, proteins and fat. Even the sweeper class were on a much better diet than the Assam coolies. Their main cereal was wheat and the quantity of milk available for consumption was about 8 oz. per head per day. In spite, however, of their better diet, particularly as regards calcium, the incidence of caries was over 30 per cent. The number of those with enlarged tonsils was also high. The average heights and weights of the children were above those of the Assam and rural Bengal groups.

An increase in the cultivation of green vegetables and consumption of dāls among the poorer classes, it is said, would be a cheap and simple expedient at least to prevent the appearance of xerophthalmia.

NUTRITION OF INDIAN POPULATION

THAT the lowest production and consumption of milk and milk products is shown by Bihar and the Central Provinces and the highest by the Punjab, and that only a fifth of the total population of India obtains the minimum physiological requirement of milk and its products, are among the facts revealed in investigations financed by the Imperial Council of Agricultural Research to obtain precise information on the production and consumption of milk by Indian cultivators, so that measures may be adopted for better nutrition of the population through a proper breeding policy.

Effective optimum

The enquiry was conducted on the suggestion of H. E. Lord Linlithgow whose dictum is that 'any race of men must be below par in direct ratio as the consumption of milk by the child, and to a great extent (particularly in a country of deficiency diets) by the adult, falls below the effective optimum'. He points out that the breeding policy which is recommended to cultivators should aim at producing a cow which yields enough milk to rear a good calf and to provide a sufficient margin for human consumption. The enquiry embraced the consumption of not only milk but also of other dairy products and the tracts selected were those where working bullocks were also produced.

The provincial governments co-operated in working the scheme. The villages and holdings in each specified area were selected at random according to the statistical principles explained in the Bowley-Robertson report. The questionnaire was designed to ascertain as much information as possible regarding the cattle bred and maintained in each area and the production and consumption of milk. And subsidiary tables were supplied to record the large amount of data.

Village conditions

The enquiry was to be conducted within a period of three months in over 50 to 60 villages in each area, by a staff of one supervisor and ten investigators for each area. In view of the enormous amount of work on the programme, the advisory board extended the period to five months. On an average twenty holdings were chosen in each village and the investigator had to stay in each holding for seven consecutive days recording the yields of milk of each cow and buffalo and noting its disposal. The supervisors were mostly selected from the permanent staff of local governments who have had experience of livestock work. Investigators were generally those relieved from the enquiry regarding cost of cultivation, an extensive scheme financed jointly by the Imperial Council of Agricultural Research and Indian Central Cotton Committee. The staff thus had some previous experience of conducting such work. The total cost of the scheme for the seven areas was approximately Rs. 25,000.

Supervisors were given practical training at Delhi before the enquiry was actually started. Prior to starting actual work each supervisor called together the ten investigators under him and imparted a course of instructions similar to that he had received in Delhi. After the field enquiry was complete the supervisors again assembled in Delhi, where the collected data were scrutinized and all calculations checked. The reports submitted by the supervisors were then scrutinized by the provincial directors concerned.

Thus the data collected are actual records of cattle living in village conditions. They are closely in agreement with the figures obtained in the survey conducted by Major-General Sir John Megaw for the whole of India and the personally controlled survey conducted by Dr. D. C. Wilson of the food habits of 30 urban and 30 rural families in the Sialkot District.

Consumption differences

The Montgomery Tract records the highest consumption of milk and milk products, namely 15.53 oz. per head per day. Hariana and Kankrej follow with 12.39 and 12.07 oz. respectively. Kosi consumes 9.71 oz. and Ongole 8.73 oz. Central Provinces and Bihar are at the bottom (as they are in production) with 6.73 and 5.51 oz.

Considering the seven tracts together 16 per cent of the families in India do not receive any milk or milk products, 36 per cent consume the equivalent of between 0 and 8 oz. milk per head per day, 26 per cent between 8 and 16 oz. and the remainder or 22 per cent receive over 16 oz. Assuming that the minimum physiological requirements of the people, large proportion of whom is vegetarian, are between 15 and 35 oz. per head per day the proportion of families which obtain this quantity is only a fifth of the total. This figure represents only the important breeding tracts and not the whole of India. Since breeding tracts should be expected to produce and consume more the all-India consumption is likely to be less.

No consumption of milk

Kosi shows the largest proportion which does not consume any milk or milk products, the percentage of non-consumers being 32.2 per cent or about a third of the total. The lowest proportion of non-consumers is in the Kankrej tract where there are only 5.9 per cent who do not receive any milk or milk products. The other areas are in the following order: Hariana, 6.9 per cent; Ongole, 9.9 per cent; Montgomery, 13.1 per cent; C. P., 21.7 per cent; and Bihar, 23.2 per cent. Ongole, Bihar and C. P. are below and Kankrej, Kosi, Hariana and Montgomery are above the all-India average proportion of 22 per cent which receive the minimum physiological requirements of milk and milk products. The model consumptions in the different areas also vary.

The above figures of total consumption of milk and milk products do not include skim-milk (*lassi*), figures for which also are given in the Council's Bulletin no. 22.

Milk yield

The highest average for cows is in Montgomery with 4.72 lb. per day in the seventh month of lactation, the Ongole cows follow with 4.61 in the sixth month and then comes Hariana with 4.46 in the fifth month. The differences between these are not, however, large and it may be safely stated that these three are approximately at the same levels of production, yielding 4 to 5 lb. per day on an average. Cows in Central Provinces are the poorest yielders, their yield being only 1.67 lb. or a little over a third of the Montgomery cows. Kosi and Bihar are between these two extremes, the former (3.89 lb.) approaching the Hariana and the latter (2.74 lb.) approaching Central Provinces.

In the case of buffaloes the order of merit is different. The Hariana tops the list with 11.21 lb. per day. Montgomery and Kankrej which follow with 8.24 lb. and 7.97 lb. respectively are only about 75 per cent as good as the Hariana. The next respectable yields are Kosi 7.06 and Ongole 6.53 lb. Bihar and Central Provinces are again at the bottom with only 5.4 lb. each per day. Generally speaking, these two areas are the worst in point of milch animals.

The large majority of cows in India, or 63.3 per cent of the total, yield less than 4 lb. of milk per day, 30.8 per cent yield between 4 and 8 lb. and only about 6 per cent yield more than 8 lb. Amongst buffaloes the low yielders form only 19 per cent while 66 per cent yield between 4 and 12 lb. per day and 15 per cent over 12 lb.

Interesting data on the consumption of milk and different milk products separately by the two sexes and at different ages, the relation between production and consumption of milk, the rate of decline in milk yield, proportion of cows and buffaloes in milk, and the size of holdings, number of work animals, milch animals and dependents per holding, are included in the Bulletin.

The Council's Advisory Board has accepted and the Governing Body has approved of the Standing Breeding Committee's recommendations designed to secure better supply of fodder, better organized marketing for live-stock and milk and milk-products laying down a breeding policy so as to increase milking capacity of females of draught breeds and urging efforts for the production of milk cheaply in India.

SURVEY OF NATIONAL NUTRITION POLICIES, 1937-38

THE work of the League of Nations on the problem of nutrition, which has already created such wide public interest, has now been carried a stage further by the publication of a book of 120 pages, entitled 'Survey of National Nutrition Policies, 1937-38'. This study is of interest not only to those directly concerned with the problem of nutrition but to the general public of the various countries covered. It is written in a style which is readily comprehensible to the ordinary man or woman.

The Survey opens with a chapter on the progress of the work of the League in regard to nutrition problems. In addition to examining a number of technical questions, it is shown that the Technical Commission on Nutrition has given practical help to Governments. It has, for example, furnished advice in regard to the planning of a minimum emergency diet for the feeding of refugees in Spain.

In Chapter II, concerning National Nutrition Committees, the creation of which was recommended by the League, it is pointed out that such committees now exist in over twenty countries. Only three committees were in existence when the League enquiry started.

A chapter on the most suitable methods of making nutrition surveys is followed by another which is of special interest, since it gives details regarding the surveys undertaken and the results obtained in various countries. There is a section of several pages on the United Kingdom, where extensive surveys are now

being carried out. It will be recalled that these were referred to by the Prime Minister in his speech in the House of Commons during the debate on the Address on 8th November last.

Australia is another country about which particularly interesting information is given, and there are also sections on other British countries—New Zealand, Canada, South Africa and India.

This chapter is full of illuminating facts about food habits in various countries. It is stated that, in an enquiry in the United States among the families of wage earners and clerical workers, from 40 to 60 per cent of the diets of white families in four regions were found to be in need of improvement. In Hungary, it has been found that, if exports are to remain unchanged and if requirements are to be fully met, the present production of milk would need to be increased by 120 per cent and of eggs by as much as 470 per cent. In Bulgaria the peasant is said to be definitely underfed during the busy agricultural seasons, while the bread which provides 79 per cent of the total energy value of his diet, is often unfit for human consumption. An enquiry in Norway showed that 53 families out of a total of 301 did not use any whole milk at all during the four weeks of the investigation. A good many villages of Yugoslavia observe practically all the Orthodox fasts, which may amount to as many as 206 days in the year. These are only a few of the facts brought to light in chapter IV, which deserves to be read by the intelligent layman who wishes to keep abreast of the problems of our times.

Chapter V, on Special Research, is of interest principally to experts, but the following one, dealing with action taken to improve nutritional standards, can be read and appreciated by all. It contains a brief description of the numerous measures taken in various countries to increase the consumption of milk, to provide cheap food to the poor, to feed school children, to improve the nutrition of mothers and young children and so on.

In the next chapter, reference is made to certain of the economic aspects of the nutrition problem. It is suggested—and a striking illustration of this from Hungary is given—that measures of relief only touch the fringe of the problem, and the Survey indicates other possible measures for making good dietary deficiencies.

In the concluding chapter, the steps taken to educate the public in various countries are described. Much can be accomplished by means of education and publicity since, as the Survey points out, 'it is surprisingly common to find relatively well-to-do sections of the population living on poor diets when, for an expenditure within their means, they could, by the wise choice of foodstuffs, obtain all the constituents of a good diet in sufficient quantities'.

This Survey is an example of the type of work in which the League has already had considerable success. There is brought together in one small, readable volume a mass of facts collected from official sources in a large number of countries. It is not merely a work of reference but also a document in which even experts can learn what is being done in other countries than their own. Such a dissemination of knowledge and ideas is of real and immediate practical value.

MATERNAL MORTALITY ENQUIRY IN CALCUTTA

THAT in 96.3 per cent of maternal deaths investigated there was an avoidable factor present is one of the findings which has been put forward, as the result of a statistical inquiry into the causes of maternal mortality lately carried out in Calcutta for a period of one year by the All-India Institute of Hygiene and Public Health with a grant from the Indian Research Fund Association.

Cases of maternal deaths were collected from all female deaths between 10 and 50 years registered in the area under the control of the Health Officer, Corporation of Calcutta. Duplicate registration cards were supplied in the case of all female deaths between these

ages and on these duplicates information was provided regarding the existence of pregnancy or the puerperal state. Considerable care was taken to ensure that duplicate registration cards were received in all cases, but questions relating to pregnancy were not answered in every case. Complete accuracy is not, therefore, claimed for the series of maternal deaths.

Causes of death

Each maternal death was followed up by home visits, interviews with the doctor, midwife or *dai* who attended at the time of delivery, or visits to the institutions in which treatment had been given. The information collected was in most cases sufficient to make it possible to reach a conclusion regarding the probable cause of death and the contributory factors, and also regarding the preventability of the death. But in some cases, these conclusions were largely conjectures based on the statement of relatives, for in 11 per cent of the maternal deaths investigated no trained person had been in attendance.

Eight hundred and eighty-seven maternal deaths were investigated, of which 701 were found to be due directly to child-bearing and the rest, 186, due to diseases associated with child-bearing.

The following is a list of causes of deaths due directly to child-bearing:—

		Per cent
1. Septic abortion	33	4.71
2. Abortion (non-septic) ..	4	0.57
3. Ectopic gestation	6	0.86
4. Other accidents of pregnancy	7	1.00
5. Puerperal haemorrhage ..	74	10.56
6. Puerperal sepsis	224	31.95
7. Puerperal alb. and convulsions	126	17.97
8. Other toxæmias of pregnancy	15	2.14
9. Embolism and sudden death ..	11	1.57
10. Other accidents of child-birth	26	3.71
11. Other or unspecified conditions of the puerperal state ..	10	1.43
12. Anæmia	165	23.53

Puerperal sepsis, anæmia and eclampsia stand out as the most important causes of death due directly to child-bearing in Calcutta, while pulmonary tuberculosis was responsible for 40 per cent of deaths from diseases associated with child-bearing.

Anæmia

The importance of anæmia was greater than appears from the table, for in addition to those deaths from anæmia *per se*, there were many others, specially in the sepsis group, in which anæmia was an important contributing factor. Very little information was forthcoming regarding the ætiological factors and the types of anæmia responsible for this mortality. A further enquiry was accordingly undertaken with the object of collecting information regarding factors which cause anæmia, *e.g.*, diets, economic conditions, purdah, personal history and associated diseases, in a series of moderately and severely anæmic women attending the welfare centres, maternity homes and antenatal clinics in Calcutta. It is hoped to discover, by means of blood examination at intervals in pregnancy and after delivery, the types of anæmia which occur and the effect of pregnancy and lactation on the course of the anæmia.

It has been found necessary to collect a control series of specimens of blood from healthy Indian women in order that the normal range of absolute values may be available for comparison. The findings so far collected suggest that the blood of healthy Indian women conforms to accepted European hæmatological standards.

Ætiological factors

Each case of anæmia and pregnancy needs to be followed up for several months and a large number of cases must be collected before any conclusion can be drawn regarding the influence of ætiological factors.

In 161 antenatal and 12 puerperal women examined there were 77 cases of macrocytic anæmia, 41 cases of

microcytic anæmia, and 55 cases of normocytic anæmia. Of the 77 cases of macrocytic anæmia only 23 were hyperchromic, the remaining being normo- and hypochromic according to European standards.

There were 40 cases of severe anæmia and of these 18 were macrocytic, 12 microcytic hypochromic and 10 normocytic normo- or hypochromic. The 18 macrocytic cases included only 7 with hyperchromia, the remaining being normo- or hypochromic according to European standards. In the series of 18 severe macrocytic anæmias there was a history of malaria in 6 cases although no parasites were found in any case. The spleen was enlarged in 10 cases and an indirect positive van den Bergh reaction was obtained in 12 cases.

CURRENT ACTIVITIES OF THE HEALTH ORGANIZATION OF THE LEAGUE OF NATIONS

The Far Eastern Bureau of the Health Organization

THE main function of the Bureau which the health committee set up in Singapore in 1925 is to keep permanently in touch with port health authorities in Eastern and Far-Eastern countries, and give immediate warning, by the swiftest available means, of all epidemic outbreaks involving a risk of contamination for the outside world. Every week, the Bureau's epidemiological communique is issued and broadcast by nine wireless stations; each of these messages, until superseded by the next, is repeated daily by the powerful station at Malabar (Java). It can be picked up at any point in the Indian Ocean and the Western Pacific, in the Mediterranean basin, and as far as the Atlantic coast. The information broadcast is constantly brought up to date.

A difficulty arose at the end of 1937, when the Bandoeng, Saigon, and Antananarivo stations gave up long-wave transmission. As a result of this, some health authorities in the Near East, on the East-African coast and in Australia were unable to pick up the message.

To meet this difficulty, the Radio-Nations station at Geneva will broadcast once a week. It will be transmitting every Friday, beginning on 10th February at 8-40 a.m. G. M. T. on wavelengths of 16.23 and 20.6 metres. This arrangement has been made in consultation with the ports concerned, but is merely tentative and subject to modification if circumstances require.

There is another aspect to the work of the Singapore Bureau, considered as part of the machinery of the Health Organization; this consists in promoting practical co-operation between public health services in the East, and between institutes engaged in research.

Thus, it devolves upon the Bureau to help forward and co-ordinate the action taken upon the recommendations of the 1937 conference of Far Eastern Countries on Rural Hygiene held in 1937.

Information supplied to the advisory council of the Singapore Bureau in November 1938, shows that the Netherlands Indies, French Indo-China, Malaya, the Philippines and Siam are now undertaking in a number of typical districts the surveys recommended by the Bandoeng conference, enquiring into the actual state of the public health, the factors affecting it, the health equipment and the working of the various health agencies. The Singapore Bureau will keep in touch with those countries, supply them with information, and endeavour to secure as much uniformity as possible in the presentation of the findings.

The Philippine authorities have recently set up a nutrition institute which is to concentrate on experimental research. India possesses a similar institution: the Nutrition Research Laboratory at Coonoor, Australia, French Indo-China, the Fiji Islands, New Zealand and Siam have also started research institutions dealing exclusively with problems of nutrition. In this way, effect is being given to a further recommendation of the 1937 conference, which after emphasizing the importance of nutrition as a

health problem in eastern countries stressed the need for dietary surveys undertaken in collaboration with the Technical Commission of the Health Organization. Since 1938, two new members representing technical institutions in Far-Eastern countries have been added to this body, which will have to co-ordinate an extensive programme of work in that part of the world.

Unification of pharmacopœia

The potential value of the creation of a limited international pharmacopœia has long been realized by medical men and is frequently brought home to the individual patient by the difficulty he experiences in getting his prescriptions made up when abroad. The same problem exists with regard to the treatment of ships' crews calling at different ports and the replenishment of ships' medical chests.

From the academic point of view, the existing variations in the strengths and composition of medicinal preparations in different national pharmacopœias add an unnecessary complication to the investigation of the comparative results in drug therapy of the same disease in different countries, and further tend to prevent the adoption of new methods of treatment by a country, even where these have proved valuable elsewhere.

Apart from the view of the practitioner, consideration must also be given to the manufacturer who, from one country, is supplying large quantities of drugs to the international market. The varying standards as to strength and particularly as to purity at present existing make it essential for a producer, either to limit his sales to his own country, or to manufacture a special preparation of the same drug for each country to which he is exporting.

The field of possible unification of pharmacopœias had already been explored by an International Conference meeting at Brussels in 1925, the outcome being a Convention creating an International Secretariat under the Belgian Government. In addition, the International Pharmaceutical Federation had worked along similar lines. A further step forward was taken in 1937, when, after agreement with the Belgian Government and in liaison with the International Pharmaceutical Federation, the Health Organization set up a Technical Commission of Pharmacopœial Experts. This commission met in Geneva during 1938 and prepared a programme of studies, including the selection of suitable drugs for examination.

The commission further considered and adopted standard forms of monograph for use in preparing the drafts, and decided to prepare general descriptions of reagents and analytical procedures, and statements of other general principles for the unification of monographs. The preparation of a report on maximum doses and on the possibility of defining average doses was entrusted to two members of the commission.

Finally, the members agreed to prepare a number of draft monographs on various drugs, 60 of which have already been received. The monographs will be subsequently considered at a meeting of the commission in May 1939, when the final form will be discussed and approved, and will then be forwarded to the Permanent Secretariat in Brussels for circulation amongst the signatory countries of the agreement, with a view to their ultimate adoption and final incorporation into a limited international pharmacopœia.

• ——— SNAKE-BITE

THE anti-snake-bite serum prepared by the Central Research Institute at Kasauli is now in demand in Burma, Iraq, Ceylon and Iran which amongst themselves bought 698 tubes in 1937. The general demand for the product continues to rise.

The product is a bi-valent serum prepared against the venoms of the Indian cobra and Russell's viper, which are the snakes probably responsible for the majority of deaths occurring from snake-bite in this

country. The increase in annual issues is shown by the following figures:—

				Tubes
1933	4,342
1934	5,973
1935	5,983
1936	7,170
1937	7,773

Further studies have been made on the methods of concentration designed to eliminate fractions which are not of neutralizing value and which tend to produce a deterioration in the physical characters of the serum when kept in the plains for prolonged periods during the hot weather.

Besides cobra and Russell's viper, the venoms of which are neutralized by the anti-venom serum, a snake which is responsible for a large number of deaths annually is the common krait. There would be no difference in principle in preparing an anti-venene for the venom of the snake, but practical difficulties exist in immunizing the horses used for the present bi-valent serum.

The chief difficulty is in obtaining a sufficient and constant supply of krait venom. The snake is difficult to keep in captivity and to feed, and so far no reliable source of supply of venom has been found.

BULLETIN OF THE HEALTH ORGANIZATION, VOL. VII, NO. 4

THE Bulletin of the Health Organization of the League of Nations (Vol. VII, No. 4) gives information concerning the activities of the organization.

Among other items, the volume contains two reports of outstanding interest. The first is a report by the Commission on Physical Education, drawn up at a meeting held in Geneva in July 1938. This report will repay study by all who are interested in scientific research relating to physical education. The commission suggests a programme of laboratory research on the physiological effects of physical exercise and on the relations between intellectual and physical development. In addition it enunciates some general principles for the use of those taking part in physical exercise and gives a draft examination form to be used for the medical examination of persons engaged in physical training.

The other report of particular interest is one dealing with certain technical aspects of nutrition. The question of the guiding principles to be observed in the study of diets and the nutrition of populations is specially dealt with, together with certain special considerations which should be taken into account in regard to nutrition in the Far East, in tropical countries and in colonial territories. Furthermore, attention having been drawn to the fact that there exist in Europe circumstances so critical as to necessitate emergency measures against famine, the authors of the report have suggested diets, very simple and inexpensive, but adequate to maintain life and to avoid severe malnutrition.

BULLETIN OF THE HEALTH ORGANIZATION, VOL. VII, NO. 5

THE Bulletin of the Health Organization of the League of Nations (Vol. VII, No. 5), which contains information concerning the activities of the Organization from August to October 1938, is specially devoted to the question of biological standardization.

This number reproduces an important report on the meeting of the serologists of the Permanent Commission on Biological Standardization held at Paris in October 1938. The report is accompanied by a number of annexes relating to tetanus antitoxin, anti-snake venom serum and gas gangrene antitoxins. The volume also contains studies on the international standard of vitamin B and the report on the Third International Conference on the Standardization of Hormones, held at Geneva in August 1938.

TROPICAL DISEASES BULLETIN

We have received the following announcement regarding the policy of the *Tropical Diseases Bulletin*:—

The broken continuity of the text in a collection of abstracts tends to make an abstract journal read like a dictionary, so that few people find that they get real satisfaction from its perusal. To overcome this disadvantage to some extent it has been decided, from January 1939 onwards, to preface each section of abstracts in the *Tropical Diseases Bulletin* by an introductory *précis* in connected narrative form of the abstracts which follow in the section. Thus a reader will be able to ascertain quickly and with ease from this brief narrative account the salient information contained in fuller detail in the individual abstracts which follow.

It has also been decided to issue in the *Tropical Diseases Bulletin* from January 1939 onwards a series of articles which will review the advances made in tropical medicine from year to year. This series of articles will bear the title "Summary of Recent Abstracts", and each article will give a connected account of the abstracts on a particular subject which have appeared in the volume of the *Tropical Diseases Bulletin* for the preceding year.

We cannot help feeling that these new features will enhance still further the popularity of this most invaluable publication.

UNIVERSITY OF CALCUTTA
NOTICE

Senate House, the 6th February, 1939

APPLICATIONS are invited from candidates for the 'Darbhanga Research Scholarship' for the year 1939.

The scholarship will be awarded for the purpose of encouraging original research in Medicine in its various branches, and all Graduates and Licentiates in Medicine and Surgery of the University of Calcutta are eligible to compete for the same. The value of the scholarship is Rs. 50 a month tenable for one year only.

The terms and conditions of the award of the scholarship will be found in the University Calendar for the year 1938, pages 269 to 270.

Applications with full particulars, as required under the rules, should be submitted so as to reach the undersigned not later than 1st May, 1939.

B. B. DUTT,
Controller of Examinations.

LONDON SCHOOL OF HYGIENE AND TROPICAL
MEDICINE

The Annual Malaria Control Course for Laymen (Engineers, Planters, etc.) will be held at the above address, commencing on Monday, 26th June, 1939, at 10 a.m.

(1) THE course will be under Sir Malcolm Watson and staff of the Ross Institute of Tropical Hygiene.

(2) The course lasts five days, and ends on Friday, 30th June, 1939. Except on Friday, 30th June, the lectures of the Malaria Control Course are given in the mornings only; but (in response to numerous requests from those who have attended in the past) additional afternoon lectures and demonstrations have been arranged on (a) water supplies, (b) conservancy and sewage disposal, (c) insulation against heat and cold, air conditioning for comfort in the tropics. The afternoon lectures and demonstrations will be given by Dr. G. P. Crowden and Mr. H. H. Clay.

(3) The course is designed for planters and mining engineers, but it will be of interest to all (including missionaries) who are proceeding to the tropics. Doctors may attend, but the course is primarily for laymen.

(4) It includes instruction on mosquitoes and their habits, drainage and other measures for the prevention of malaria. It is illustrated by lantern slides, films,

demonstrations of the living insect in the various stages of its history, and a practical demonstration on Hampstead Heath.

(5) The course is free. Application to attend the course should be sent in as early as possible to the organizing secretary at the above address.

(6) The most convenient underground railway stations serving the School are Tottenham Court Road, Goodge Street, Russell Square.

(7) Luncheon can be obtained at the school.

H. LOCKWOOD STEVENS,
Organizing Secretary.

HUNTERIAN SOCIETY

Gold Medal for Practitioners

Any registered general practitioner resident within the British Empire is eligible to compete, and the medal, which is of gold, is awarded annually to the writer of the best essay on a subject selected by the Society.

Competitors—men or women—must be engaged in general practice and essays should be sent in by December 31st.

The essay must be unpublished and original, and be based on the candidate's own observation, but it may contain excerpts from the literature on the subject, provided that reference be made to the articles from which they are taken.

A copy of the rules and any further information can be obtained on application to the Honorary Secretary, Mr. Alex E. Roche, 140, Harley Street, W.1.

The subject selected for the Essay is:—

1939. 'The Treatment of Obesity in General Practice.'

1940. 'The Treatment of Tonsillar Infections in Children.'

The 1938 Hunterian Gold Medal for General Practitioners was won by Dr. James E. Outhwaite, of Yeadon, Leeds, for his essay on:—

'The Management of Inoperable Malignant Disease in General Practice.'

THE TINNEVELLY DISTRICT MEDICAL ASSO-
CIATION, PALAMCOTTAH (TINNEVELLY
BRANCH OF THE INDIAN MEDICAL ASSO-
CIATION)

Monthly meeting

THE monthly meeting of the Tinnevelly District Medical Association was held under the presidency of Lieut.-Colonel T. S. Shastri, I.M.S., at the Government Hospital, Nanguneri, on Saturday, the 28th of January 1939. Members numbering 30 were present at the meeting.

The secretary and treasurer read the minutes of the annual re-union which was celebrated on the 3rd of December 1938, which were passed.

It was decided to invite Madura, Ramnad and Travancore Medical Associations to hold a joint meeting with the local association at the next monthly meeting at Palamcottah.

A resolution was unanimously passed congratulating the Honourable Dr. T. S. S. Rajan, Public Health Minister of the Government of Madras, on the passing of the Public Health Bill by the Madras Legislature.

Resolved that the Indian Medical Association should be officially recognized by the Government of Madras and that the orders may be issued that the association must be consulted on all important matters relating to public health and medical profession as well.

Dr. M. Vaidyanathan, L.M.P., of Nanguneri, showed a child of 3 years who is suffering from a very complicated state of congenital syphilis.

Dr. T. K. Nilakanta Iyer, L.M.P., read out the following cases, which were successfully treated at the Government Headquarters Hospital, Palamcottah:—

1. A case of acute abdomen.
2. A case of fracture of pelvis.
3. A case of myelitis.

The skiagrams relating to the above were demonstrated. Each case was fully discussed by the members.

Thereafter Lieut.-Colonel T. S. Shastri, I.M.S., summed up the salient and important features of all the cases and their differential diagnosis in detail. He offered his cordial thanks to Dr. M. Vaidyanathan, L.M.P., for the arrangements.

Thereafter an excellent dinner party brought the happy gathering to a close at 10 p.m.

Health exhibition

Under the auspices of the Timmervely District Medical Association in connection with the monthly meeting, a health exhibition was arranged at the Board High School, Nanguneri, on the 28th of January 1939 at 10 a.m.

Lieut.-Colonel T. S. Shastri, I.M.S., welcomed the guests and declared the exhibition open.

The exhibition was kept open till 1 p.m. The exhibits consisted of posters on tuberculosis, smallpox, fly danger, cholera, etc. The exhibits of the school were also exhibited.

ISTITUTO NAZIONALE PER LE RELAZIONI CULTURALI CON L'ESTERO

POST-GRADUATE MEDICAL COURSES IN ITALY

THE I. R. C. E. (National Institute for Cultural Relations with Foreign Countries) has organized courses for medical graduates from abroad, who may wish to keep abreast of the latest developments of Italian medical science. (1) Such courses are scheduled for the month of June, taking place in Rome, from 5th June to 17th June, after which they adjourn to Bologna, Pavia and Milan until the 22nd.

The present programme will deal with those particular subjects in which Italian medicine has reached an outstanding position either on scientific or on practical lines; and will present:

(a) Six short courses of 6 to 8 hours each on: surgery, hæmatology, malariaology, orthopædies, phthisiology and 'corporative' social medicine.

(b) Lectures on scientific subjects by Professor Raffaele Bastianelli, Sir Aldo Castellani, Professor Cesare Frugoni, Rev. Father Agostino Gemelli, Professor Rodolfo Margaria, Professor Nicola Pende, Professor Luigi Preti and Professor Pietro Rondoni.

(c) Lectures on public health organization and preventive medicine: O. N. M. I. activities (National Organization for Mother and Child Welfare); health services of the G. I. L. (Fascist Youth Organization); land reclamation ('bonifica integrale'), etc.;

(d) Visits to scientific institutes; public health achievements; field-trips to the Agro Romano and Pontino, and so forth.

Lectures will be held in Italian, but summarized translations as well as an interpreter will be available on application.

The tuition fee amounts to 300 lire, inclusive of trips to the reclaimed areas.

All the facilities granted to the students of the I. R. C. E. language and culture courses will be provided for the medical courses as well.

For detailed schedules please apply to the I. R. C. E. Via Lazzaro Spallanzani 1A, ROME.

Applications for the courses must be filed before 1st May, 1939.

Rome, 30th January, 1939.

THE BALKAN MEDICAL UNION

THE Balkan Medical Union is essentially a scientific organization. But it also represents an ideal. Its aim is to bring together the intellectuals of different countries so that they may know each other and come to a mutual respect and understanding, and in this way form a compact block capable of opposing the misunderstanding that engender hate and disastrous struggles between nations.

This 'Union' was formed in 1931 by a handful of men sincerely convinced that this humanitarian aim

could and should be easily attained. Their conviction is based on the belief that this object is in the line of human evolution and that in helping this evolution the forward march can be hastened.

For intellectuals who have known how to see and grasp that which is the essence of humanity what more beautiful ideal can be thought of than to work with all their faculties, all their energy to establish an understanding between men.

It is through the 'Medical Weeks' that our Balkan Union tends to realize these aspirations.

Athens, Belgrad, Bucarest, and Istanbul, each in turn have seen more and more numerous and enthusiastic groups come together, all permeated by the same desire of comprehension and friendship. We doctors know that a very small quantity of vaccine can protect millions of men from the danger of contagious diseases. So the good seed scattered by the Balkan Medical Union is a real remedy against the evils set loose by human passion.

Prof. Dr. ^A Akil Moukhtar Özden.

UNQUALIFIED PRACTITIONER SENTENCED

THE Subdivisional Magistrate, Khanewal, convicted Mr. Abdul Rahman under section 6 of the Indian Medical Degrees Act, 1916, for using the letters 'L.M.P. and L.C.P.S.' after his name without any lawful authority.

THE WILLIAM GIBSON RESEARCH SCHOLARSHIP FOR MEDICAL WOMEN

MISS MAUD MARGARET GIBSON has placed in the hands of the Royal Society of Medicine a sum of money sufficient to provide a Scholarship of the yearly value of £292, in memory of her father, the late Mr. William Gibson of Melbourne, Australia. The Scholarship is awarded from time to time by the Society to qualified medical women who are subjects of the British Empire; and is tenable for a period of two years, but may in special circumstances be extended to a third year. The next award will be made in June 1939.

In choosing a scholar, the Society will be guided in its choice 'either by research work already done by her, or by research work which she contemplates. The scholar shall be free to travel at her own will for the purpose of the research she has undertaken'.

There is no competitive examination, nor need a thesis or other work for publication or otherwise be submitted. The Society has power at any time to terminate the grant if it has reason to be dissatisfied with the work or conduct of the scholar.

Applications should be accompanied by a statement of professional training, degrees or diplomas, and of appointments, together with a schedule of the proposed research. Applications must be accompanied by testimonials, one as to academical or professional status, and one as to general character. Envelopes containing applications, etc., should be marked on top left-hand corner 'William Gibson Research Scholarship' and should be addressed to Mr. G. R. Edwards, Secretary, Royal Society of Medicine, 1, Wimpole Street, London, W.1., and be received not later than Thursday, 1st June, 1939.

THE FACULTY OF RADIOLOGISTS

THE British Association of Radiologists and the Society of Radiotherapists of Great Britain and Ireland have decided to amalgamate under the title of 'The Faculty of Radiologists'. The work of the Faculty will be carried on at the old office of the British Association of Radiologists at 32, Welbeck Street, London, W.1.

BELGIAN SOCIETY FOR TROPICAL MEDICINE, ANTWERP

THIS Society has recently conferred the honour of 'Membre-correspondant' on Brevet-Colonel R. N. Chopra, C.I.E., K.H.P., M.D., Sc.D. (Cantab.), F.R.C.P. (Lond.), I.M.S., Director of the School of Tropical Medicine, Calcutta.

Current Topics

Short Notes on the Failures of Uleron

By J. HARTUNG

(Abstracted from the *Münchener med. Woch.*, Vol. 85, No. 49, 1938, p. 1899)

THE author observed of undesirable effects in his first series (700 cases), one case of neuritis, one of gastritis, one of icterus and nine exanthemata, a figure which was reduced to only three cases of exanthemata due to Uleron when the doses were subsequently modified. The gradual disappearance of by-effects in clinical experience runs parallel with the decrease of Uleron-resistant cases. Hartung showed that with the introduction of short concentrated courses the percentage of failures was markedly less than with high protracted doses. However, allowing a proportion of resistant cases to any form of treatment there still evidently remained a number of cases in which Uleron did not produce a cure. These failures were apparently due to a wrong technique. Various explanations have been brought forward. In some patients endoscopic examinations of the urethra proved helpful to explain the cause of Uleron resistance. These cases usually showed small purulent glands in the urethra which were absent in those patients who readily responded to Uleron. It seems reasonable that in these cases the higher and protracted dosage would not improve the results but may increase the risk of by-effects. The removal of these purulent glands by cauterization made the Uleron resistance disappear and the patients were eventually cured by the same drug.

Opinions concur that although gonococci disappear from the urethra after the first four days' course ('stoss') of Uleron they may persist in the para-urethral ducts, and no increase or repetition of dose will change this state of affairs. Cauterization of the para-urethral ducts and inflamed Littre glands seems to be the best procedure to achieve ultimate cure.

Hartung, not satisfied with the rather crude empirical finding that Uleron is evidently more successful in the sub-acute and chronic cases than in acute infections, has subjected all his cases to the gonococci-complement-fixation test (CFT) and found that the results were particularly good when the CFT was positive, in other words when the organism had already acquired a certain amount of immunity. In uncomplicated gonorrhoea the CFT becomes slightly positive after a fortnight and increasingly so later on. Comparative results showed that the response to Uleron was in general better in direct proportion to a positive CFT. Comparing the number of patients treated, it was found that in cases with slightly positive CFT the first Uleron 'stoss' gave about 83 per cent cures, whereas with a negative CFT the cures amounted to only 36 per cent. Drawing his conclusions from these figures Hartung decided to produce a positive CFT as early as possible to make the patients amenable to Uleron treatment and he did so by stimulating the immunization process by the use of specific vaccines. A gonococcal vaccine was injected in very small initial doses of 20 mill. germs on the first day, 40 mill. on the third, 80 mill. on the fifth, 160 mill. on the seventh and 200 mill. on the ninth day which eventually resulted in a positive CFT. Thereafter allowing a few days to lapse, the Uleron 'stoss' was given, the cure rate being 80 per cent.

When applying this form of treatment in all cases, it means giving up the rather spectacular abortive effect which was sometimes achieved with a single Uleron 'stoss' of four days in cases of acute gonorrhoea to the extent of about 25 per cent of all cases. Theoretically it seemed reasonable to modify the whole treatment in the way that one Uleron 'stoss' was given first to get the benefit of the 25 per cent immediate cures and to treat the remaining 75 per cent according to the above vaccine-Uleron method. Hartung when

putting this theory to the test however found that the remaining 75 per cent who had received already an Uleron treatment without any vaccine proved to be rather refractory and in further treatment the cure was protracted in an unusual way. The author concluded that the advantage of the 25 per cent immediate success should better be foregone in favour of the less striking combined vaccine-Uleron treatment with an average cure-rate of 80 per cent although it meant the extension of the course which otherwise would last four days to an average of a fortnight up to three weeks.

It seems, in view of the above, that much more research and exact clinical observations are necessary to arrive at a definite appreciation of the value of Uleron and other sulphonamide preparations in the treatment of gonorrhoea. Already now there is sufficient evidence to show that Uleron is a definite advance in the treatment of this disease which apart from its value *per se* has stimulated valuable investigations into the much disputed immuno-biological processes in gonococcal infections.

Hiccup

(From the *Lancet*, Vol. II, 19th November, 1938, p. 1212)

Hiccup is one of those complaints which, like mumps and sea-sickness, is apt to be considered a joke by everyone except the sufferer himself. Actually, except in its most transitory forms, it is always distressing, and, in its post-operative and epidemic types in old people, may prove fatal. The great majority of cases owe their origin to acute or chronic dilatation of the stomach, with or without intestinal meteorism, but the less common causes are legion. Dr. A. H. Douthwaite divides them into three classes. Of the first, the central causes, the most important are uræmia—especially after prostate operations, when reflex irritation from the operation site or from meteorism is a contributory cause—and hysteria, also usually post-operative. This group also includes the intractable hiccup met with in epidemics of encephalitis lethargica, and the toxic forms seen in pneumonia and typhoid. In the second class the condition is secondary to irritation of the phrenic nerve, very rarely from lesions in the neck, sometimes from mediastinal pleurisy, tumour or pericarditis, or from a diaphragmatic hernia, sub-diaphragmatic abscess or secondary deposits in the liver. The third class, the reflex, is the most common. This may arise in the stomach, as in children who bolt their food and in sufferers from gastritis and the indigestion of over-smoking; in the intestines, from distension or the irritation of thread-worms; and possibly in the prostate and liver.

Many of the forms of treatment are empirical and have been devised by sufferers themselves—for example, the induction of sneezing (as Bason observes) or vomiting, drinking from the wrong side of a tumbler, holding the breath, or applying a tight binder to the epigastrium. 'The hicket', writes a sixteenth-century doctor, 'is cured with sudden feare or strange news'; another maintains that 'it is good to caste colde water in the face of him that hathe the hicket'. Turning to more drastic remedies, the phrenic nerve may be attacked directly by firm pressure above the clavicles or by the injection of procaine at the same site. One of the most effective methods is the inhalation of 5 to 7 per cent of carbon dioxide in oxygen, or, more simply, breathing in and out of a paper bag. Morphia is justifiable for persistent cases, and may be life-saving in the epidemic variety. Where there is dilatation of the stomach lavage usually gives relief. Meteorism may be relieved by passing a flatus tube or giving 1 to 5 c.cm. of prostigmin or 0.5 to 1 c.cm. of pituitary extract. In post-operative cases it is important to reduce the fluid intake which has often been pushed to excess. In the milder forms associated with vague indigestion and flatulence carminatives such as sal volatile may help. Drugs are on the whole disappointing, though many are recommended.

Finally, in hysterical hiccup, careful explanation, combined with some impressive procedure, or the mere suggestion of stomach lavage, may work wonders, but hypnosis may be necessary in a few obstinate cases. Fortunately most patients will recover spontaneously before many of the formidable list of therapeutic measures have been tried.

The Treatment of Vaginal Discharge in General Practice

By W. F. T. HAULTAIN, O.B.E., M.C., F.R.C.S. (Edin.),
M.R.C.P. (Edin.), F.C.O.G.

(From the *Medical Press and Circular*, Vol. CXC VII,
23rd November, 1938, p. 468)

ONE of the commonest gynaecological complaints which a general practitioner is called upon to treat is vaginal discharge, so-called leucorrhœa, though this nomenclature is not strictly accurate for the number of various types of discharge which may be found. Up to a few years ago the general treatment of leucorrhœa consisted of vaginal douches with various kinds of antiseptics, and, whilst they gave temporary benefit owing to their cleansing effect, the discharge was seldom cured unless douching was persisted in almost daily. No antiseptic has yet been found which, by means of constant douching, would destroy the offending organisms and not have a similar destructive effect on the vaginal walls, thus intensifying the already present discharge: in some cases the cessation of antiseptic douching and a douche of saline or boiled water would cure a discharge which had been present for years due to constant irritation of the vaginal walls. During the last few years a large amount of work has been done not only on the ætiology and pathology of vaginal discharges, but also on the physiology of the normal vaginal secretion. By such investigations the treatment of pathological vaginal discharge has made great progress, the great aim being, after destroying any pathological invasion, to get the condition of the vaginal mucosa back to normal again and, if this can be attained, the discharge is permanently cured unless reinfection occurs.

Vaginal discharge may occur at three different periods of a female's life: (a) before puberty; these cases are very rare and are either due to illicit intercourse or, more commonly, to uncleanliness and dirt; (b) during the child-bearing period; and under this heading one can group (1) in married women, (2) in virgins; and (c) after the menopause—so-called senile vaginitis. It is, however, cases under group (b), and especially of married women, that form the great bulk of the cases who complain to their medical attendants, and it is these which will be chiefly considered. Cases of true gonorrhœal discharge will not be touched upon, in the first place because it is without the scope of this paper and, in the second, because such discharges definitely proved to be due to the gonococcus are apparently very rare indeed and many that used to be thought to be due to such a cause are really infections by the *Trichomonas vaginalis*, which has now been proved to be such a common offending organism.

When a patient attends complaining of a vaginal discharge, the first thing to note is the character of the discharge, i.e., its colour, odour, viscosity, etc.; secondly, the state of the vaginal mucosa itself—is it normal to look at, or is it definitely inflamed, or are there reddened discrete patches studded over the mucosa and cervix? Is there marked irritation of the vulva and the surrounding structures caused by the discharge? Thirdly, is there an erosion or eversion of the cervix present, or, possibly, a small mucous polypus protruding? And lastly, is there any urethral discharge as well? The nature of the discharge is, in the first instance, all important as a tenacious, viscid discharge is always chiefly cervical in origin, whether or not any erosion is found, and thus local treatment to the vagina is absolutely useless, and the only way to treat such a condition is to treat the endocervicitis which is present,

and this can only be done effectively by cauterization with the electric cautery, though some people prefer the diathermy current. An offensive discharge very often denotes that constipation is an accompanying feature, and if it be treated then the odour disappears and frequently the discharge as well. An acute vaginitis, vulvitis and urethritis may denote gonorrhœa, but a subacute vaginitis associated with irritation around the vulva is frequently due to trichomonal infection, as is also the case in the vagina which is studded by discrete red patches. A smear should be taken from the vagina in all doubtful cases, a sterile smear being taken by means of a platinum loop if gonorrhœa is suspected, but for a trichomonal infection a smear of the discharge collected on the examining finger, smeared on a slide and stained by Leishman's stain for 20 minutes and then washed off with water, will show up trichomonas if they are present: the old hanging drop method, which was difficult to do and to obtain positive results, is not necessary now as staining, as above described, seems to be more efficacious and is certainly very much easier to do.

If there is no vaginal irritation and if the discharge is white and not purulent, it is important to know if the discharge is due to a local vaginal condition or some general cause, such as debility, anæmia, avitaminosis, etc. This can usually be done by testing the pH of the discharge, which can now be easily carried out with the universal indicator of B.D.H., an equal quantity of the discharge and the colouring agent being smeared on a slide and the colour of the resultant mixture compared with the colour table on the bottle. The normal vaginal discharge is acid, having been made so by the lactic acid formed by the action of the vaginal bacilli (Döderlein's) on the glycogen, which is produced by the action of oestrin on the vaginal mucosa. The normal pH is in the region of 4.4, and if the discharge is due to general causes the pH. is not greater than 4.4 to 4.6; over that amount, however, the discharge is definitely due to pathological invasion and it would seem that trichomonal infection gives the highest pH 5.8 to 6.8. If the discharge is due to general causes, then general treatment, usually of some duration, is solely required and as the patient's condition improves so does the discharge.

For the consideration of treatment, pathological vaginal discharges can be divided into three main classes, according to their severity. In the mild cases the application of lactic acid to the vagina is often sufficient and the treatment is easily carried out. This can be done by daily douching with lactic acid (1-500), or better with sour milk diluted half and half with water, as this supplies the lactic acid bacilli as well as the acid itself. An easier method is to prescribe a pessary containing lactic acid, such as spuman pessaries with lactic acid: two of these are inserted into the vagina on alternate nights after a boiled water douche on three occasions, and this is followed by a further similar course, using one pessary instead of two; a last douche is given 48 hours after the insertion of the last pessary so as to get rid of any debris. This treatment has been found to be efficient in the cases of white discharge causing discomfort but which is not very profuse or discoloured.

In the more moderate cases the dry method of treatment following antiseptic swabbing is usually efficacious and can be easily carried out in the consulting room or the patient's home. The treatment is carried out as follows: a bivalve or single speculum is inserted and the vagina cleansed by swabbing with soda bicarbonate solution; it is then dried and painted all over either with picric acid, 2 per cent, or dettol (pure); the vagina is now very thoroughly dried and then insufflated with an inert powder, such as dermatol powder, the chief constituent being bismuth subgallate. This is done daily for several days, then on alternate days, every third day, and lastly, once a week, the whole treatment lasting about one month, but many cases are cured before this time.

The severe discharges, especially those associated with vaginal redness and vulval irritations which are

usually purulent and frothy, are commonly due to *Trichomonas vaginalis*, and this organism has proved to be very resistant to the usual forms of treatment. They, however, seem to be destroyed by arsenical or silver preparations, but, unfortunately, though apparently cured, recurrences are frequent, especially following a menstrual period or intercourse. The most simple way of treating such a condition is by means of arsenical tablets or pessaries, which can be inserted by the patient herself; many of these are on the market and have proved to be efficacious in a large number of cases, but they must be given in a sufficient dosage to cure the condition. Though this is usually quite a safe form of treatment, I have seen one or two cases of mild arsenical poisoning result from their use in cases where the vagina seemed to be especially absorptive to arsenic, and therefore cases so treated must be carefully supervised so as to detect such a condition arising at its very beginning. Some cases, however, need a more intensive treatment, and for the last two years two methods have been tried out in the gynaecological clinic under my charge.

The first method consists, in the first instance, of insufflation of the vagina, after it has been dried, with a silver picrate powder, the preparation used being Pieragol and the insufflator used being that of Wyeth Bros., which I have found to be very satisfactory, especially as it is used without a speculum and can be inserted into the narrowest introitus without causing pain or discomfort. After the insufflation has been done, Pieragol pessaries are inserted, one daily for a week, after which a second insufflation is carried out followed by a further course of a week's treatment with pessaries. Usually this is sufficient to clear up the discharge, temporarily at any rate, but in some cases a further course is required after the next menstrual period is over.

The other method is by means of Stovarsol; the vagina is insufflated with Stovarsol powder, and this is done each day of the menstrual period, the vagina being dried before the application of the powder. During the inter-menstruum, Stovarsol vaginal compound tablets, one daily, are inserted into the vagina and a further insufflation is given at the next period. The reason why this treatment has been carried out at the menstruation is that it has been found by Swift, in Australia, that the trichomonas seem to be actively growing then, being much smaller in size and seeming to be more active if a film is examined from the discharge at that time.

Both these treatments have given satisfactory results and I am not yet able to say which is most satisfactory. If one fails the other practically always succeeds, and if a patient is found to have an idiosyncrasy to arsenic, then the Pieragol is an excellent standby. On the other hand, I have seen two cases of picric poisoning or rash in women who have an idiosyncrasy to picric acid. Lately, I have followed one insufflation and course of pessaries by further pessaries of lactose, glucose and boric acid aaa gr. v , to try to restore the normal functions of the vaginal mucosa, and, though it is too early yet to say definitely, the results are very promising.

With regard to vaginal discharges, it is possible that they may also be due to trichomonas, or, as is more frequently the cause, due to general conditions. Sometimes a sticky white discharge is present which is very persistent, and it is often found that this is due to a congenital cervical erosion, the cauterization of which will cause immediate cessation of the discharge. Another cause of ... is a hymen, which almost obliterates the introitus and allows secretion to accumulate and cause increased irritation to the vaginal mucosa. Such cases have been cured by a perineotomy, allowing free drainage.

In cases of senile vaginitis, again the trichomonas may be the causal factor, but most frequently the discharge and vaginal inflammation are due to a decrease of oestrii secretion and the administration of large doses of oestrii, say 50,000 I. B. U., twice weekly will, in practically every case, cause the vagina to become normal again and the discharge to cease. Such cases,

however, should always be curetted in the first instance to exclude a carcinoma of the body of the uterus; during the last year I have diagnosed three such cases, where the only symptom was a purulent vaginal discharge with no bleeding. In a small number of cases of senile vaginitis a small mucous cervical polyp is found, which is the causative factor, but there is still the possibility of the presence of a carcinoma of the body of the uterus in such cases as well.

From those remarks it will be seen that the treatment of the purely vaginal discharges can be carried out efficiently and well by the general practitioner, either in his own surgery or in the patient's home, and it is only the very few persistent cases which require hospital treatment.

The Ætiology of Nausea and Vomiting of Pregnancy

By J. WILLIAM FINCH, M.D.

(Abstracted from the *Journal of the American Medical Association*, Vol. CXI, 8th October, 1938, p. 1368)

THIS paper is a preliminary report on work being done to prove that nausea and vomiting accompanying pregnancy are due to an allergic reaction of the patient to the secretion of her own corpus luteum graviditatis.

This symptom complex is one which has been confronting the medical profession for centuries, the first record being made by Soranus of Ephesus in the year A.D. 20.

Various authors state that in from one-half to two-thirds of all obstetric cases there is nausea and vomiting to some degree during the first few months of pregnancy. So numerous have been the theories as to the ætiology of this symptom complex that in this brief report no effort to discuss them will be made. The treatments recommended have been as variable and numerous as the theories of ætiology.

The patient exhibiting nausea and vomiting may have these symptoms as a first indication of an existing pregnancy. The symptoms almost invariably begin between the third and the sixth week of pregnancy and gradually subside some time near the fourth month of pregnancy. The symptoms may vary in severity from the mild case, so frequently seen, in which there is morning sickness with or without vomiting, to the moderate case in which there is nausea all day long, frequently vomiting, and extreme discomfort for weeks. Or the case may advance to the true hyperemesis gravidarum with a truly serious prognosis.

Hirst was the first to connect the nausea and vomiting of pregnancy with the functioning of the corpus luteum. He states that every woman during her menstrual life is constantly absorbing corpus luteum substance but that with the onset of pregnancy this absorption ceases. On this theory he administered corpus luteum extract to a number of patients with surprisingly good results in alleviating or stopping their symptoms.

The corpus luteum, with impregnation, continues to develop instead of taking on the customary retrogressive changes during and after menstruation. The corpus luteum of pregnancy develops to a size much larger than the false corpus luteum; the colloid is more abundant in the organ and the granulosa cells are larger than before pregnancy. This enlargement takes place at the same time that symptoms of nausea and vomiting develop and the patient begins to be relieved of her symptoms about the fourth month, at which time retrogressive changes are taking place in the corpus luteum.

Considering that the development of the nausea and vomiting and the development of the corpus luteum of pregnancy occur at the same time and that the time of retrogressive changes in the gland, I decided to conduct a series of tests on the theory that the nauseated and vomiting patient is allergic to her own hormone, develops her symptoms as a result of her sensitivity and returns to normal after the gland ceases to feed its secretion into her body in such quantity.

On the same theory it can be assumed that Hirst was able to relieve his patients not by giving them a secretion in which they were deficient, as he assumed, but by desensitizing them and relieving them of their allergic reaction to the hormone.

Patients were tested by cleansing the skin with alcohol and injecting intradermally from 0.02 to 0.03 c.c. of progestin in sterile cottonseed oil and recording reactions fifteen and thirty minutes later. Reactions were calibrated from negative to 4 plus, according to the size of the weal and the surrounding erythema produced just as in intradermal injections of any food, drug or pollen extract or animal dander to determine a patient's degree of sensitivity. A control injection was made with sterile cottonseed oil in the same arm. The majority of the tests were made on the volar aspect of the forearm. A few patients were tested with a solution of progestin in sterile almond oil but the cutaneous reactions to the almond oil were so much greater than those to the cottonseed oil that the latter product was used in the remainder of the cases. One interesting notation has been that several of the pregnant patients who were nauseated and gave 3 or 4 plus reactions to the progestin intradermally have complained as late as five or six weeks after the intradermal injection that when they become nauseated severely the area of injection again becomes irritated and forms a weal with a surrounding erythema and an itching sensation. I know of no way to explain this other than that the solution injected, being an oily one, is absorbed very slowly, and part of it remains in the skin for a protracted time. An extremely high percentage of the patients with nausea and vomiting of pregnancy gave a family history of allergy.

COMMENT

This is only a preliminary report, but I believe that the uniformity of the results of the intradermal tests, the good results on the patients treated along the lines of allergic desensitization and the huge number of women afflicted with these symptoms at all times merits an investigation on a large scale. It would also be of interest to test with intradermal progestin a series of young girls before puberty.

I believe that patients presenting nausea and vomiting either have inherited directly a sensitivity to progestin or, more probably, have inherited the allergic tendency and become sensitive to their own corpus luteum secretion during their menstrual cycles or from the corpus luteum of a previous pregnancy.

If further investigation confirms these observations, one might well assume that a patient desiring pregnancy could be tested for sensitivity to progestin and, if found sensitive, could be desensitized before impregnation or before the corpus luteum of pregnancy reaches the stage of enlargement necessary to produce the symptoms of nausea and vomiting. This treatment would consist of graduated doses of progestin injected at closely spaced intervals until the patient is desensitized and the symptoms either do not develop or are relieved if they have already developed. It would be of further benefit, I believe, if a solvent other than oil could be used for the progestin, since the various oils now in use are more or less irritating to the skin of patients when injected intradermally and are slowly absorbed. A solution less irritating and more quickly absorbed would probably also enhance the treatment of nausea and vomiting along these lines by allowing intradermal injections to be given concurrently with the subcutaneous injections for desensitization.

SUMMARY

1. Nausea and vomiting of pregnancy develop at the same time at which the corpus luteum of pregnancy reaches an appreciable size. The symptoms disappear at about the time the gland is known to begin retrogressive changes.

2. In a series of patients with nausea and vomiting of pregnancy in varying degrees when injected intradermally with from 0.02 to 0.03 c.c. of progestin in oil a cutaneous reaction developed directly proportional to the severity of the symptoms.

3. A control series of patients who were not nauseated and in the pregnant state gave negative cutaneous reactions when tested in the same manner.

4. Patients treated with subcutaneous corpus luteum extract and progestin along the lines of allergic desensitization were gradually relieved of their symptoms.

5. A high percentage of the patients with nausea and vomiting of pregnancy either had other diseases of allergy or gave a family history of allergy.

CONCLUSIONS

1. The nausea and vomiting accompanying pregnancy is due to an allergic sensitivity of the patient to the secretion of her own corpus luteum of pregnancy.

2. Desensitization may be accomplished by injection of graduated doses of progestin, thus alleviating or stopping the patient's symptoms.

3. Intradermal testing may determine, even before pregnancy, whether a patient will or will not be nauseated when pregnant by determining whether or not she is sensitive to progestin.

A New Chemical Contraceptive

By JOHN R. BAKER, D.Sc.

R. M. RANSON

and

J. TYNEN

(Abstracted from the *Lancet*, Vol. II,
15th October, 1938, p. 882)

AFTER introducing hexylresorcinol and other substances into practical use, we spent much time exploring the possibility of using other phenol derivatives, especially the parahydroxybenzenes. During the course of our work at this time we added a very small amount of a well-known organic mercury compound to one of our gelatin gels in order to inhibit bacterial growth and were surprised to find a marked increase in spermicidal power. This particular substance presents certain disadvantages, but as the result of investigating other organic mercury compounds we discovered phenyl mercuric acetate to be the most spermicidal substance in weakly acid solution of any that we have ever tested. Its killing concentration is 1/1024 per cent in acid and 1/256 per cent in alkaline media. Phenyl mercuric nitrate has a killing concentration of 1/1024 per cent in both acid and alkaline media. It must be stressed that these are not simply the most spermicidal harmless substances, but absolutely the most spermicidal substances known, the acetate heading the list in acid and the nitrate in alkaline solution. A killing concentration of 1/1024 per cent makes these substances no less than 512 times as spermicidal as quinine bisulphate and chinolol, which have been used so much in chemical contraception.

PREPARATION AND TESTS

Since a solid product was desirable, for convenience of handling, and since the spermicide must be in solution in water, we have worked with gelatin gels. For the spermicide we have preferred phenyl mercuric acetate to the nitrate. Although the latter is the more spermicidal in alkaline media, it possesses disadvantages which outweigh this advantage and would outweigh it even if the mixed semen and vaginal fluid were alkaline. Actually there are reasons for supposing that the semen may usually be changed somewhat to the acid side of neutrality by the lactic acid of the vaginal fluid. We have succeeded in making a permanently stable solution of the acetate in the water of our gels by buffering at about the pH of human semen. A powerful dispersive agent in emulsion is added to give rapid mixture with semen, and little glycerol to make the whole product approximately isotonic with the body fluids. It has been a principle with us for some years that a chemical contraceptive should not be widely different in osmotic pressure from blood. Many commercial preparations are extremely hypertonic, and

water drawn into the vagina may not only dilute the spermicide but also give undue lubrication. An account of the method of preparation of our product will be published elsewhere.

The final product is designated as P.383. The gels are cast as discs, each weighing 2.5 grammes. They are lightly dusted with starch grains to prevent their sticking to one another or to the glass tube in which they are packed. The gels are unsuitable, however, for use in hot climates without special cool storage, as they melt when warmed to near the temperature of the body. (The melting-point being close to that of dairy butter, the conditions under which that can be stored may be taken as a guide for the storage of gels, which however must not be frozen solid.)

The total spermicidal powers of these gels have been compared with those of the best-known contraceptive suppositories on the market. The tests of spermicidal power of suppositories are carried out in the same way as those of pure substances, except that the concentrations are differently expressed. Tests are made at the 'standard' or S concentration of one suppository to 6 c.cm. of fluid (which is thought to be about the usual amount of fluid in the vagina after ejaculation), and at half, one-quarter, etc., of this concentration (S/2, S/4, etc.). It may be mentioned that every detail of these tests was settled before we had discovered the high spermicidal power of phenyl mercuric acetate.

The gels designated as P.383 have, according to these tests, a killing concentration of S/8. Of the ten well-known contraceptive suppositories which we have tested, three have a killing concentration of S/2 and three of S, while four fail to kill at S.

In acid media P.383 is even more spermicidal, with a killing concentration of S/16. If it were desired the spermicidal powers of these gels could be still further increased by adding more phenyl mercuric acetate, but it has been thought unnecessary to exceed S/8 and S/16 in alkaline and acid media respectively.

Since the rate of escape of the spermicide from the vehicle is as important as the total spermicidal power, a special diffusion test is carried out, in which mechanical mixing of the product with the semen is avoided. Observations are made at 2, 5, 15, 30 minutes, etc., up to 3 hours.

Four other makes of suppository on the market were compared with P.383 in the diffusion test. P.383 has the most rapid rate of diffusion: marked diminution of activity was observed in two minutes and all the sperms were generally dead (not merely immobilized) in five. Two of the marketed products which we tested diffused so slowly that scarcely any effect was observed on the movement of the sperms after an interval of half an hour and some activity was still evident after three hours. These were the two products which showed the best results in the test of total spermicidal power of all the ten which we compared with P.383. With the third proprietary product which kills at S/2, some sperms were still alive at 15 minutes in the diffusion test. It would be waste of time to apply the latter test to those suppositories which failed to kill even at S in the test of total spermicidal power, in which all the killing power extractable from the product is made use of for action on sperms, without any reliance on the diffusive power of the product.

Repeated trials showed P.383 to be harmless to the vagina and cervix of the bitch. As usual, in order to make the test stringent, we placed half the human dose in the vagina daily (except on Sundays) for a fortnight, and the bitch was then killed and the vagina and cervix sectioned and examined microscopically by Dr. Carleton. The gels were then distributed to clinical workers for practical test under medical supervision. Their reports on the æsthetic qualities of the gels are favourable.

CLINICAL TRIALS

One of us has pointed out the unreliability of reports on clinical tests of the effectiveness of contraceptives. One can never be certain that the product is used in the right way—e.g., before and not

after coition—nor even that it is used at all on every occasion. It is not certain that any chemical contraceptive, however spermicidal, could ensure safety to a multiparous woman with a patulous or split cervix, in the absence of an occlusive pessary.

It is important to stress the fact that the great majority of the women who tested the gels had already borne children, many of them being very fertile and having had repeated pregnancies (up to a maximum of 12) before starting to use P.383. The woman who became pregnant is multiparous and has a split cervix.

In addition to the women there are many who have used the gels alone or in various combinations, but about whom there are no exact data except that they have not reported themselves pregnant. One doctor alone has distributed over 2,500 gels in this way, over a period of a year, without a pregnancy being reported to him. There are also 15 women whose husbands have used sheaths while they have used the gels. One woman in this category has become pregnant, but the clinical worker doubts whether in this particular case the gels were actually used.

The standards which we have tried to realize in P.383 are the following:—

1. It should be inexpensive.
2. It should be solid, and therefore require no special appliance for insertion into the vagina.
3. It should be small.
4. It should be unaffected by the ordinary range of climate.
5. It should neither leave any trace on the skin when handled, nor stain fabrics.
6. It should contain no volatile nor odorous substance.
7. It should be non-irritant to the vagina, cervix, and penis.
8. It should be without pharmacological effect if absorbed into the blood stream.
9. It should contain a substance reducing surface tension, to ensure the smallest crevices of folds of the vagina being reached.
10. It should kill sperms at S/8 or lower concentration in the alkaline and acid tests for suppositories, and the spermicide should diffuse rapidly out of the vehicle into semen.

Dickinson and Bryant use a closely similar list, but require also that it must not be easily displaceable.

It may be claimed that P.383 satisfy all these requirements, provided that the words 'ordinary range of climate' refer to Great Britain and other cool parts of the world. With regard to the requirement that the product should not be easily displaceable, it may be stated that P.383 are fluid when melted at body temperature, but we have found that sticky vehicles prevent that rapid diffusion of the spermicide which is so essential for success.

Reviews

THE BRITISH ENCYCLOPÆDIA OF MEDICAL PRACTICE—INCLUDING MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY AND OTHER SPECIAL SUBJECTS.—Under the General Editorship of Sir H. Rolleston, Bt., G.C.V.O., K.C.B., M.D., D.Sc., D.C.L., LL.D. Volume IX. Butterworth and Company, Limited, London. Pp. xxix plus 752 plus 53. Illustrated. (To be completed in 12 volumes. Sold in complete sets only. Cash price, Rs. 25 per volume.) Also available on the instalment system at Rs. 26-8 per volume. Payable Rs. 10 monthly. Only available from Messrs. Butterworth and Company (India), Limited, Calcutta

THIS volume deals with subjects from mumps to pneumothorax, and includes chapters on a number of matters of considerable practical importance to practitioners in any country, namely, on pneumonia (lobar)

by Dr. R. A. Young of the Middlesex and Brompton Hospitals, on peptic ulcer by Thomas Hunt of St. Mary's Hospital, and nephritis and nephrosis by Dr. Izod Bennett.

The chapter on lobar pneumonia is orthodox and up to date; no details are given of the treatment by MB. 693, but Whitby's experimental work and Evans and Gaisford's successful clinical trials (this latter reference must have been a last-minute addition, as the paper was only published last July and this volume was received in India in November) are included. Neither digitalis nor alcohol are recommended for routine administration, but the value of oxygen is stressed: either the oxygen tent or the nasal catheter is recommended, and the rate of flow of oxygen in the case of the latter is given as 4 to 16 litres per minute.

In the chapter on peptic ulcer there is a well-balanced discussion on the different methods of treatment. The criticisms on the histidine treatment of this condition are moderate and certainly fair. Medical treatment, with of course a dietetic regime, is given preference; the indications for surgical treatment are the usual ones, but the writer considers that medical treatment should be given more than one chance unless definitely contra-indicated.

Another important chapter from the practitioner's point of view is that on peritonitis. This is contributed by three writers; Dr. Zachary Cope deals with acute peritonitis, Dr. C. E. Lakin with chronic peritonitis, and Dr. C. E. Kellett with tuberculous peritonitis in children.

There are two chapters on medico-legal subjects—the first on that interesting subject, disputed paternity and blood groups. The test is of course one for non-paternity, and it can never be more than that. It may prove that a man is wrongly accused, but never that the woman's accusation is correct. The other subject is professional negligence: this is a chapter that should be read by all practitioners; it is of course based on English law, but much of it is equally applicable in this country.

Of the chapters on tropical diseases the most important is that on plague by Dr. L. F. Hirst, who for many years worked in Colombo and made a special study of this subject. He gives a good account of plague from the historical, epidemiological, bacteriological, and clinical points of view. One is a little disappointed to find no reference to the histopathology of plague; this is a point about which most writers are very reticent. Sand-fly fever is described concisely but adequately by Air Commodore H. E. Whittingham, who did some useful original work on the breeding of sand-flies in Malta some years ago.

There is a good account of pellagra by Colonels J. Heatly-Spencer and A. G. Biggam. The recent work on nicotinic acid is included, but no special recommendations as to dosage are given, it is probably too early, even now, to be dogmatic on this subject; the important point is that small doses will often cure (100 mgm. daily) and that much larger doses are usually well tolerated. They stress the importance of giving vitamin B₃ for the associated neuritis.

All the articles in this volume are sound, practical and well presented.

A MANUAL OF REPARATIVE PLASTIC SURGERY.—By J. E. Sheehan, M.D., F.A.C.S. 1938. Oxford University Press, London. Humphrey Milford. Pp. xxi plus 311, with 314 illustrations and 18 full-page plates. Price, 30s. Obtainable from Oxford University Press, Bombay and Calcutta

Surgeons will welcome Professor Sheehan's second book, in which he presents an up-to-date review of the principles of plastic surgery together with a description of those operative procedures which he has found by experience to be most suitable.

An early chapter is devoted to forms and conditions of choice of skin grafts, in which prominence is given to the advantages of the free graft of intermediate thickness, and of the 'delayed' pedicle flap. Noteworthy, also, is the condemnation of the pinch graft which is dismissed as a 'surgical error' on account

of the clumsy result produced in both recipient and donor areas.

About half the book deals with the orbit, nose, and facio-maxillary regions with admirable clarity and a refreshing brevity not usually displayed by American writers. But in this section of the book instances can be given where an unimportant procedure could be omitted to give room to a more important one. Thus, the ophthalmologist will pass over the description on how to remove a pterygium, but will look in vain for hints on how to close a corneal fistula.

Or the rhinologist will find small interest in the description of septal resection, but will get no help in the problem of repair of a septal perforation.

The concluding chapter describes the treatment of miscellaneous conditions, and could well have been omitted or, better still, considerably expanded, as it upsets the balance of the whole book. For example, McIndoe's operation for hypospadias is the only genito-urinary plastic operation presented. Lastly, ophthalmic surgeons in this country will look on the section on corneal grafting and smile, for they have been doing better than this for some time past.

The illustrations and diagrams are numerous and excellent, and the script is clear, although there are a few annoying misprints.

W. McN. N.

THE STUDENT'S HANDBOOK OF SURGICAL OPERATIONS.—By Sir F. Treves, Bart., G.C.V.O., C.B., LL.D., F.R.C.S. Sixth Edition. Revised by C. P. G. Wakeley, D.Sc., F.R.C.S., F.R.S.E., F.A.C.S. (Hon.), F.R.A.C.S. 1939. Cassell and Company, Limited, London. Pp. xl plus 563, with 246 illustrations. Price, 12s.

The Student's Handbook of Surgical Operations by Sir Frederick Treves is already well known to the reviewer who found it a book of great value both when he was a student and later for reference when he was qualified.

It is eight years since the last edition was published and the present one has been brought thoroughly up to date. It includes amongst other additions, the newer operations on the brain and spinal cord and the various forms of osteotomy and arthrodesis. The number of illustrations have also been increased and are of great value in elucidating the text.

Mr. Wakeley is to be congratulated on the way he has revised this excellent, practical and concise book on operative surgery, which in my opinion is quite the best of its kind and should be in every student's possession.

F. W. A.

CANCER: WITH SPECIAL REFERENCE TO CANCER OF THE BREAST.—By R. J. Behan, M.D., Dr. Med. (Berlin), F.A.C.S. 1938. Henry Kimpton, London. Pp. xvi plus 844, with 168 illustrations. Price, 42s.

LACKING a single monograph embodying descriptions of the 'complex and varied changes which are associated with the different phases of cancer', Dr. Behan made a detailed study of the known facts and theories, resulting in the production of an excellent volume. This book was originally written as a treatise on mammary carcinoma, but, in order to make it more useful, its scope was increased to include a comprehensive knowledge of malignant disease in general. The breast shares with the uterus the distinction of being the commonest site of carcinoma, about 40 per cent of all carcinomata occurring in this gland. According to the United States census of 1935 mammary carcinoma caused 13,226 deaths which formed 9.2 per cent of the total mortality of that year. It seems fair to conclude that, at any given time, at least 65,000 women in the United States alone are suffering from mammary carcinoma. It has been estimated that in the civilized countries of the world 500,000 persons die of cancer each year. These figures reveal a telling picture. The author believes that in the study of the 'alterations in the biological activity of the individual cancer cell' lies the greatest chance of success for a more effective method of treatment.

There are 29 chapters in this book, the first five are devoted to the consideration of aetiology, pathology, and biochemistry. The next five chapters deal with symptomatology, diagnosis and biopsy and there are two chapters on the subject of metastasis. Prognosis is not a matter about which the present-day surgeon can feel at ease, for modern post-operative results do not show any appreciable improvement on the past. Treatment, therefore, has received very careful attention in this book. There is no question of operative treatment *versus* irradiation; in carcinoma of the breast there can be no disputing the fact that, in the absence of metastasis, surgery is best. The author lays down the dictum that irradiation is applicable in rapidly growing neoplasms in young subjects, in pregnant or debilitated women, and in widely disseminated inoperable new growths. The author is emphatic that a patient with mammary carcinoma should not be permitted to undergo pregnancy or even to continue menstruation, which is certain to augment the condition. He is of opinion that pregnancy should be interrupted as an urgent measure and menstruation eliminated by temporary castration by means of irradiation.

We have read this book with pleasure and profit, and we cannot recall any other book which gives so much information on the subject of mammary carcinoma. The illustrations are excellent but depressing. The many pictures of advanced carcinoma make one wonder whether it will ever be possible to achieve contact with patients in the earliest stages of the disease. For discouraging results, the surgeon is not alone responsible; the family physician holds the pivotal position. Carcinoma must be diagnosed early, and in early radical operation lies the surest chance of cure. We strongly recommend this book to the medical profession and, in particular, to the general practitioner in this country where the problem of malignant disease is of no less magnitude than in the West.

PYE'S SURGICAL HANDICRAFT: A MANUAL OF SURGICAL MANIPULATIONS, MINOR SURGERY, AND OTHER MATTERS CONNECTED WITH THE WORK OF HOUSE SURGEONS AND OF SURGICAL DRESSERS.—Edited by H. Bailey, F.R.C.S. (Eng.). Eleventh Edition. 1939. John Wright and Sons Limited, Bristol. Pp. viii plus 512, with 362 illustrations. Price, 21s.

Pye's Surgical Handicraft edited by Hamilton Bailey is a manual of surgical manipulations, minor surgery, and other matters connected with the work of house surgeons and of surgical dressers.

The contributors, all well-known authorities, have revised a book which has already stood the test of over fifty years' publication and in so doing have produced a handbook which fully fulfils the purpose for which it was intended—namely, a practical guide for house surgeons and surgical dressers.

It is well illustrated, easy to read and full of wisdom; and I do not hesitate to recommend it to the busy practical man.

F. W. A.

UROLOGY.—By D. N. Elsendrath, M.D., and H. C. Rojnck, M.D. Fourth Edition, entirely revised and reset. 1938. J. B. Lippincott Company, Philadelphia and London. Pp. xxi plus 1061. With 750 black and white illustrations and 12 in colour. Price, 42s. Obtainable from Butterworth and Co. (India), Ltd., Calcutta. Price, Rs. 28-0

It is hardly necessary to offer any introduction to this well-known work on urology. The reception given to previous editions is ample endorsement of the authors' efforts. Recent advances in both diagnostic and therapeutic methods have necessitated thorough revision of the text and inclusion of new material. Some of the newer features deserve special mention. A critical evaluation of excretion urography as a diagnostic method together with its advantages and limitations has been clearly set out. The chapters on

venereal diseases have been brought up to date, but paradenitis (lymphopathia venereum), however, is only briefly described. Recent studies on male sex hormones and gonadotropic principles found in urine have been included under appropriate sections.

The growing importance of cystometry in the diagnosis of neurological disturbances of the urinary bladder has led the authors to include an interesting chapter on the subject. Some emphasis has been laid on the frequency of non-operative stricture of the distal portion of the ureter in the female sex. It is an observation worthy of careful attention. The importance of urology in women and children has been recognized and there are additional chapters on this subject. The section on operative technique will be much appreciated; it is replete with valuable practical hints. The method of trans-urethral resection in case of enlarged prostate has been clearly indicated.

This book may rightly be regarded as a standard work of reference and we have much pleasure in commending it to the notice of the medical profession in this country. We have no doubt that the present edition will meet with as cordial a welcome as that of its predecessors. The printing, get-up and illustrations are excellent; the appendix, and the references in the footnotes will be found useful.

P. N. R.

INTRODUCTION TO OPHTHALMOLOGY.—By Peter C. Kronfeld, M.D. 1938. Charles C. Thomas, Springfield, Illinois, Baltimore, Maryland. Pp. ix plus 331. Illustrated. Price, \$3.50

THIS introduction deals principally with the pathogenesis of disease. The details of diagnosis, of methods of examination, and of treatment have been omitted as the author considers they can be more effectively given in the form of oral instruction combined with demonstrations *in vivo*. A large number of common diseases have been omitted altogether from the book because they are unimportant according to the author for the exposition of ophthalmological principles. Short descriptions of these diseases will be found in the dictionary which is combined with the index of the book.

The book consists of 307 pages divided into 16 chapters dealing with an anatomical introduction, the diseases of the anterior adnexa of the eyeball, the diseases of the cornea, uveitis, endophthalmitis, the crystalline lens, injuries, the physiology of the retinal circulation, the vascular diseases of the eye, the intra-ocular pressure and its pathological variations, neoplasms, the optic nerve, the visual pathway, the pupil, the motor anomalies of the eye, refraction and finally an index and ophthalmological dictionary.

At the end of each chapter the author includes an extensive bibliography. The book is well written and amply provided with excellent illustrations, although pictures of external diseases of the eye have purposely been omitted as the author considers they are poor substitutes for the living specimen.

The book is different from the ordinary run of small textbooks on ophthalmology, contains much valuable information and forms most interesting reading.

We recommend it to students of ophthalmology as a book well worthy to be included in their library.

E. O'G. K.

HANDBOOK OF OPHTHALMOLOGY.—By Humphrey Neame, F.R.C.S., and F. A. Williamson-Noble, F.R.C.S. Third Edition. 1939. J. and A. Churchill, Limited, London. Pp. xiv plus 332, with 12 plates containing 46 coloured illustrations and 143 text-figures. Price, 13s. 6d.

THIS is the third edition of this handbook, which alone is sufficient evidence of its popularity and usefulness. The book is intended for undergraduate students and general practitioners. The authors have dealt with the diseases of the eye and its adnexa which are seen in the out-patients' department and have included brief descriptions of the commoner ocular conditions found among medical in-patients; they have

confined themselves to brief notes upon the uncommon affections and omitted all reference to the rarities of ophthalmology.

The book consists of 320 pages divided into eighteen chapters dealing with the examination of the eye and its surroundings, the refraction and accommodation, the eye-lids and lacrimal apparatus, injuries of the eyeball, the conjunctiva, the cornea and sclerotic, the iris, ciliary body and choroid, the lens, the vitreous, the retina, the optic nerve, the extra-ocular muscles, the orbit, operations, signs and symptoms in general, in the tropics and therapeutics. There is also an appendix on requirements of candidates for admission into the public services, a glossary and finally an index.

In the third edition the chapter on tropical ophthalmology has been modified and enlarged. A section on vitamins in diseases of the eye has been added to the chapter on general diseases.

A short article in the uses of contact lenses has also been included.

The book is excellently brought out and well supplied both with coloured illustrations and text-figures. It is written in clear simple style and we recommend it as a useful textbook for students and medical men working in India.

E. O'G. K.

A GLASGOW MANUAL OF OBSTETRICS.—By S. J. Cameron, M.B., F.R.F.P.S., F.C.O.G., John Hewitt, M.B., Ch.B., F.C.O.G., R. A. Lennie, M.D., F.R.F.P.S., F.C.O.G., and E. D. Morton, M.B., Ch.B., M.C.O.G. Third Edition. 1939. Edward Arnold and Company, London. Pp. viii plus 678. Illustrated. Price, 21s.

DR. CAMERON and his colleagues have written an excellent book. The authors indicate in the preface that their object is to provide 'a book which might prove helpful to the student and practitioner'. This object, we think, has been well achieved.

The views of the authors have been clearly expressed throughout the text. These are in accord with the modern and accepted ideas on the many subjects discussed. We note and appreciate the excellent résumé of such controversial subjects as the factors responsible for the onset of labour, use of pituitary extract in labour, and the very valuable description of the general treatment of puerperal sepsis with sulphonamides.

The chapters on radiology in obstetrics and the post-natal treatment by physiotherapy are novel features of this book. It is unnecessary to emphasize the importance of these subjects in modern obstetrics. The authors will earn the gratitude of all for whom this volume is meant.

We have little but praise for this book. We must, however, say that we cannot agree with the authors' recommendation of internal podalic version in a case with placenta prævia, nor should we put down in a students' textbook that 'It is quite proper to apply forceps to make a careful attempt at delivery with the patient in Walcher's position when a considerable portion of the head has passed the obstruction, although the longest diameters are yet above the brim'. These are perhaps the personal and well-tryed views of the authors, experienced as they are.

The book is well printed and bound. It is profusely illustrated with clear figures well chosen to describe the matter contained in the text.

It is an excellent book for the undergraduate and the obstetrician.

M. S.

THE EVOLUTION OF OBSTETRIC ANALGESIA.—By A. M. Claye, M.D. (Leeds), F.R.C.S. (Eng.), F.C.O.G. With a Chapter by W. S. Sykes, M.A., M.B., Ch.B. (Cantab.), D.A. 1939. Oxford University Press, London. Pp. 103. Price, 6s. Obtainable from Oxford University Press, Bombay and Calcutta

THIS compact little book describes in brief the efforts made to find a satisfactory drug, or combination of

drugs, to produce analgesia in childbirth, from the days of Simpson up to the present time.

There are chapters on ether and chloroform, scopolamine alone, scopolamine-morphine, the barbiturates and nitrous oxide, ethylene, and other inhalants. The barbiturates include nembutal, chloral, and pernocton.

The advantages and disadvantages of each are described, together with the technique of administration.

At the end of each chapter there is a comprehensive list of references for those who wish to follow the subject more fully, and who have the necessary access to medical literature.

This little work has much of interest and instruction for those who practise obstetrics, but it is not intended to be a comprehensive textbook on the subject of obstetric analgesia and anaesthesia.

The impression on reading it is that it could, with advantage, be expanded into such a textbook, to include analgesia administration by midwives, and anaesthesia for various obstetric operations. Such an expansion would add value to the book and little to its bulk, though a slight change in name might be necessary.

Finally, a mention of the cost of the apparatus described in the text, such as Minnitt's, would be of value to those in this country who have to administer hospitals with poor financial backing.

K. S. F.

DISEASES OF THE NEWBORN.—By Abraham Tow, M.D. 1937. Oxford University Press, London. Humphrey Milford. Pp. xviii plus 477. Illustrated. Price 27s. 6d. Obtainable from the Oxford University Press, Bombay and Calcutta

THIS study of the newborn infant is an attempt to co-ordinate the findings of the research worker and the clinician and is intended for the use of the general practitioner, the children's specialist and the obstetrician. The author is the professor of paediatrics at the New York Polyclinic. This book should prove useful for reference for it contains a great deal of compressed information, but although it contains references to cases in the author's experience the method of presentation lacks the illumination of the personal angle of approach and for this reason it makes rather dull reading. There is an extensive bibliography at the end of every chapter and for this reason alone the book is valuable.

M. N.

STUDIES ON THE SIZE OF THE RED BLOOD CELLS ESPECIALLY IN SOME ANÆMIAS.—By E. Mogensen. 1938. Oxford University Press, London, Humphrey Milford. Pp. 216. Illustrated. Price, 12s. 6d. Obtainable from Oxford University Press, Bombay and Calcutta

THIS book is the result of an elaborate study of principles and practice of Price-Jones' method of measuring the size of blood cells and of presenting his findings.

The author has followed Price-Jones' practice of taking the arithmetical mean of the two diameters of the cells in dried films measured by a method of projection. All his data, and some of Price-Jones', are subjected to the statistical method of examination and his conclusions are based on results of these examinations. On the whole he agrees with Price-Jones' conclusions and approves of his methods, but in a few instances he has pointed out weaknesses. He has introduced a method for decomposing heterogeneous Price-Jones' curves: this method, which is described, he has applied to all his curves.

Pernicious anæmia curves can be divided into three components, the main, the right, and the left component.

He has measured the cells and examined the data statistically in a number of different types of anæmia. In each case he has given his own results and discussed the findings of other observers.

Whilst one cannot help seeing the possibilities in this method of decomposing curves for purposes of

haematological research, the procedure seems to demand a little closer examination before its soundness can be accepted, as it means adding a new complication to an already laborious and complicated procedure.

Our main criticism of the book is that the author has attempted to cover too large a field: in many instances only a very few cases have been examined and his figures for normal subjects are often based on the examination of a very small number.

It is, however, a book which all interested in haematological investigations should study. To those who do not possess Price-Jones' book it has the additional value that it describes his methods in detail, and finally it has a very useful bibliography of over three hundred references.

L. E. N.

PHYSIOLOGY OF THE NERVOUS SYSTEM.—By J. F. Fulton, M.A., D.Phil. (Oxon.), S.B., M.D. (Harb.). 1938. Oxford University Press, London and New York. Pp. xv plus 675. Illustrated. Price, 25s. Obtainable from Oxford University Press, Bombay and Calcutta

THIS monograph is a lucid exposition of modern neurophysiology. The different chapters deal with the structure and functions of the different regions of the nervous system. Each chapter begins with historical notes and concludes with a detailed summary of the subject dealt with in the chapter; this summary will appeal to students. The author has included the recent advances in anatomy and physiology of the nervous system, particularly those relating to the receptors, the ventral and the dorsal nerve roots, the structure of the synapse, the cerebellum, the thalamus and its cortical projections, the hypothalamus, and the cytoarchitecture of the cerebral cortex. The physiology of the autonomic nervous system has been described in great detail.

Besides dealing with the structure and functions of the nervous system the monograph includes material that will be of help to students of clinical medicine, in the study of the diseases of the nervous system.

The get-up and printing of this volume are excellent. The book will prove valuable to the students of physiology and neurology.

P. C. S. G.

RECENT ADVANCES IN CHEMOTHERAPY.—By G. M. Findlay, C.B.E., M.D., D.Sc. Second Edition. 1939. J. and A. Churchill, Limited, London. Pp. x plus 523. Price, 21s.

A BOOK on chemotherapy dated 1930 is almost like a history of the world up to the time of the flood: this was the date of the first edition of *Recent Advances in Chemotherapy*, so that for all practical purposes the present edition is a new book.

Chemotherapy is a subject in which up to a few years ago tropical medicine definitely held a clear lead, but whether in the face of the happenings of the last three years in the field of the chemotherapy of bacterial infections this lead will be maintained seems very doubtful.

The author has not allowed himself to be overawed by this newer chemotherapy and, though the chapter on acute bacterial infections occupies nearly a third of the book, the other subjects have had their full share of attention. This chapter is however a very complete one and in the references are included the outstanding contributions from Domagk's first paper in 1935 to those that appeared late in 1938; the limitations as well as the triumphs of this new therapy are stressed and a number of sections are devoted to the rare but serious sequelæ, such as agranulocytosis and aplastic anæmia, to the administration of drugs of this group.

Of recent advances in the therapy of amœbiasis a good account is given and carbarsone is given an important place. There is a good summary of the newer antimonials, though in the treatment of leishmaniasis few compounds of importance have been introduced since the last edition. Fouadin is mentioned as of value in the treatment of *Dirofilaria*

immitis of dogs, but the only reference to its use in human filariasis is to record a failure. This has been the experience of most workers, though there is a popular theory amongst clinicians that it is of value. The chemotherapy of human filariasis does not seem to have begun yet.

The chapter on the chemotherapy of malaria is naturally an important one and one that has had to be completely rewritten since the advent of atebirin. A well-balanced account of the subject is given.

The practice of putting the references, not at the end of each chapter as is the usual practice but after each section of the chapter to which they refer, is a good one. These alone make it invaluable as a book of reference.

The writer has produced a very valuable contribution to a subject whose importance increases daily.

CLINICAL STUDIES IN PSYCHOPATHOLOGY: A CONTRIBUTION TO THE ÆTIOLOGY OF NEUROTIC ILLNESS.—By Henry V. Dicks, M.A., M.D. (Cantab.), M.R.C.P. (Lond.). 1939. Edward Arnold and Company, London. Pp. 248. Price, 12s. 6d.

IN the preface the author states that the material and most of the subject-matter of the book, originally formed a series of post-graduate lectures at the Tavistock Clinic. The Tavistock Clinic is to be congratulated on having Dr. Dicks on its staff, for his book is one of the most penetrating works on psychopathology that has appeared in English for a considerable time. The author is a practising psychoanalyst with a profound, but by no means blind, admiration for the venerable founder of psycho-analysis. In actual practice the author adheres to certain modifications of orthodox psycho-analytical procedure as introduced by Dr. J. A. Hadfield. The author is very emphatic on the part played by the mother in regard to the formation in later life of a neurosis in her child, particularly in a female child. Indeed, Dr. Dicks goes so far as to state that it might be of real psychopathological and sociological value to investigate systematically the types of parent and their relationship to each other in conjunction with the various psychogenic disorders. The records of child guidance clinics, the author thinks, ought to provide ample material for such an enquiry. Each theme is illustrated by one or more clinical histories. The author's treatment of sex dysfunction is particularly interesting, as is also his discussion of drug addiction and its treatment. In the last chapter the author strikes a hopeful note as regards the future of psychological medicine. He writes: 'The time is not now so far distant when the corpus of medicine will once again achieve its own "psychosomatic unity"'. That it ever became dissociated, was partly due to the unwholy fascination of the illusion of magical omnipotence that test-tube and microscope conjured up in the last century, which made the independent study of mental—that is to say properly human—phenomena barely even worthy of contempt in the eyes of the pundits'. To this view all psychiatrists will heartily subscribe.

THE HEALTH OF THE NATION AND DEFICIENCY DISEASES.—By John Maberly, M.R.C.S. (Eng.), L.R.C.P. 1938. Baillière, Tindall and Cox, London. Pp. xi plus 118. Price, 5s.

IT is very difficult to decide why, and for whom, the author wrote this book. Did he mean it for popular, or for medical consumption? If the former, why does he include so many prescriptions and references to medical literature, and go into such minute details about the ætiology of pernicious anæmia? If the latter, well . . . the qualified practitioner can look after himself, but we must warn the student that reliance on the information on the subjects touched upon in this book will head him straight towards failure in his examinations. The author's preface does not help one much; this leads one to think that he is going to revive the thirty-year-old newspaper 'stunt' regarding 'deadly white bread', but if this was his intention he

allowed himself to be led down side-tracks and lost sight of his original purpose. Here he also refers to the 'ruling authorities' in the East who allow the milling of rice despite the fact that they know the deadly results of this practice; this led the reviewer to hope that possibly some fresh light was to be thrown on this important problem, but there are only two short pages devoted to beri-beri and rice, and the information given is rudimentary and scrappy, and could be found in almost any textbook of medicine.

The chapter headed 'The Discovery of the Vitamins' looks promising, but it is found to consist of less than a page and a quarter of print and even this has not been used to the best advantage. He refers to the work of Lunin, of Stepp, and of Eijkman and, then he credits Casimir Frank (sic) with introducing the term vitamin; the only other name mentioned is Sir J. G. Hopkins. The concluding sentence in the chapter is 'The name vitamin B was attached to the anti-beri-beri element, and the five chief vitamins were gradually isolated as vitamins A, B, C, D and E'.

His chapter on maize and pellagra is innocent of any reference to nicotinic acid. He doubts the vitamin deficiency theory of pellagra; this conclusion appears to be based on the fact that, if you give a horse a feed of maize overnight, he is liable to bolt with you when you attempt to mount him next morning.

There are references to medical journals and books. These are sometimes given in detail in the text and repeated in the list at the end; on other occasions, they are included in the list but not referred to at all in the text. The references, as references, are in many instances inadequate.

It seems just possible that the uninformed non-medical reader might find the book of some interest.

L. E. N.

ESSENTIALS OF MEDICINE.—By Charles P. Emorson, M.D., and Nollie Gatos Brown, R.N. Thirtieth Edition. 1938. J. B. Lippincott Company, Philadelphia and London. Pp. xxii plus 845. Illustrated. Price, 12s. 6d. Obtainable from Butterworth and Company (India), Limited, Calcutta. Price, Rs. 9-6

THIS book gives the medical student or nurse an excellent groundwork on which they should be able to build their further knowledge.

Not only does this work deal with the commoner diseases and their treatment, but also, in the first chapter, gives him a brief outline of the anatomy, physiology, bacteriology, chemistry, and physics which the beginner cannot fail to understand with ease. There is also a most praiseworthy chapter on the observation of the patient, a subject to which both students and nurses could well afford to give more attention than is commonly done.

The remaining chapters dealing with the diseases of the different systems consider first, in each case briefly and clearly, the anatomy and physiology of the respective systems, and here the accompanying diagrams render the descriptions very easy to follow.

The student is nowhere worried with any difficult theories, and in each case only the important points in treatment are emphasized.

It must be realized, however, that this book has been written essentially for students and nurses in America, and therefore those studying in this country will have to supplement their reading in certain instances. Thus in the chapter on blood diseases no mention is made of tropical macrocytic anaemia, and there is only a small paragraph on anemias of pregnancy. Again, when writing on tropical diseases, for the treatment of malaria, quinine is the only drug mentioned, and the term estivo-autumnal has no advantage over malignant tertian in the classification of malaria.

This book covers the essentials of medicine in a very lucid way and can be recommended to all students and nurses.

PHYSICAL DIAGNOSIS.—By R. C. Cabot, M.D., and F. D. Adams, M.D. Twelfth Edition. 1938. Baillière, Tindall and Cox, London. Pp. xxii plus 846. Illustrated. Price, 22s. 6d. Postage inland, 7d. Postage abroad, 1s. 10d.

THE eleventh edition of this book which appeared in 1934 was kept approximately the same size as earlier editions by the omission of laboratory tests and data to permit of additions owing to the many advances that had taken place. Exclusive of the index this edition was just over 500 pages and the twelfth edition which has just been published has nearly 800 pages.

This is an indication of the great advances that have been made in diagnostic methods in recent years, but the increased size is not altogether due to this alone, because two new chapters have been added at the beginning of the book, the first an exhaustive discussion on how a history should be taken and a shorter one on general advice regarding how to conduct a physical examination.

Until the appearance of this edition the author had written the whole book himself and only included diagnostic methods of which he had personal experience. This was perhaps possible in a clinician of his great experience, but he now has to admit that good and necessary methods in modern diagnosis are being too rapidly added to be assimilated and thoroughly understood by a single individual so he has wisely called to his aid his colleagues of the Massachusetts General Hospital and has shared the burden of editorship with Dr. R. Dennette Adams. The result of this collaboration has been a much improved and much larger production which can be confidently recommended as a book of reference.

As in the earlier editions, the numerous, well-chosen and beautifully reproduced illustrations are an education in themselves and a great deal can be learnt from them without reference to the text.

P. A. M.

ADVENTURES IN RESPIRATION: MODES OF ASPHYXIATION AND METHODS OF RESUSCITATION.—By Yandoll Henderson. 1938. Baillière, Tindall and Cox, London. Pp. xi plus 316. Illustrated. Price, 13s. 6d.

THIS book mainly deals with modes of asphyxiation and methods of resuscitation. In the earlier chapters the author has discussed the rôle of oxygen and carbon dioxide in the physiology of the human system and the modern principles of shock and acapnia. The discussions on the fallacy of asphyxial acidosis and on the phenomenon of acardia deserve special mention. The book was read all through with great interest, especially the chapters dealing with mountain sickness and acclimatization, carbon monoxide asphyxia, asphyxia of the newborn and their resuscitation. The book contains a mass of information on different subjects. Incorporation of results of the author's own experience and investigations on the various lines has made the volume more attractive. It has depicted the real place of carbon dioxide in medical science. The bibliography at the end of the book is very valuable.

P. D.

MEDICAL JURISPRUDENCE.—By M. A. Kamath, M.B. & C.M. Fourth Edition. 1938. Butterworth and Company (India), Limited, Calcutta. Pp. ix plus 343. Illustrated. Price, Rs. 6.

A SMALL book like this should be all a medical student needs.

The treatment of the judicial procedure, legal responsibilities of a medical man and medical ethics is brief yet complete. Younger generations of medical men, however, would not safeguard their own interests by obtaining another practitioner in consultation by 'some pretext or other' in a case of suspected attempt at abortion. Neither would they in cases of doubt get 'on the safe side' by sending to the authorities communications marked 'private and confidential'.

Enough is given under toxicology to tell a medical man what aid can be expected from a chemical examiner.

Not all instances illustrating exceptions to the rules based on the considered opinion of the majority of medicolegal experts are taken from scientific publications. Many of them should be discarded.

The narrative is involved at times. Rectification of this defect will mean considerable labour but is worth undertaking in the next edition.

Blood groups and their bearing on forensic medicine constitute a serious omission which should not occur in the next edition.

Only two printer's errors attract attention. On page 65 *aviscus* should be a *viscus*, and on page 249 *Burkenhead* should be *Birkenhead*.

The size, the paper, the printing and the binding are good. The price is reasonable.

S. D. S. G.

Abstracts from Reports

THE EIGHTH ANNUAL REPORT OF THE ASSOCIATION FOR THE PREVENTION OF BLINDNESS, BENGAL, 1937-38

INTRODUCTION

THE Committee of the Association for the Prevention of Blindness, Bengal, with great pleasure present the Eighth Annual Report of the Association and it is gratifying to report the very satisfactory progress that has been made during the year, and encouraging to know that its activities have met everywhere with great enthusiasm due to the wonderful work it has accomplished in the prevention of blindness and the relief of human suffering.

Appeals for assistance were received in large numbers from different parts in and outside of Bengal but many had to be turned down on account of limited financial resources.

The main feature of the year was the work done by the two travelling dispensaries. As pointed out in the last annual report, in addition to the Jubilee Travelling Eye Dispensary a Second Travelling Eye Dispensary was started in East Bengal in August 1937. This dispensary commenced work in the Mymensingh District under the care of Dr. C. R. Chakraverti, and during the rainy season a boat was used instead of a motor ambulance as parts of the district were only passable by rivers. Later, as the rivers commenced to dry up, the boat was dispensed with and the dispensary was moved about by rail and country carts. The medical officers of these dispensaries carried out propaganda work in the prevention of blindness and care of the eyes by means of lantern lectures, demonstrations, cinemas, posters, pamphlets, etc. These medical officers are fully trained eye specialists and in addition carried out curative work in restoring sight to the blind. Operative work was carried out in the sub-divisional hospitals or in buildings improvised as hospitals. All operative work ceased a week before the dispensary was due to move on. A travelling eye dispensary can only stop for a period of about three months and it was often pathetic to have to refuse the appeals of the inhabitants for an extension of its stay in the district but owing to lack of sufficient money an extension could only be granted when the local community put up the money to pay for its upkeep.

During the year the Jubilee Eye Dispensary was under the direction of Dr. S. K. Das and worked in the districts of Jessore, Nadia and Dinapur, and the Travelling Eye Dispensary No. 2 worked in the Mymensingh District. The No. 2 Travelling Eye Dispensary was started in August 1937 and placed under the charge of Dr. Chakraverti, who was transferred from the Jubilee Dispensary to initiate the smooth working of the unit and very ably he has carried out his duties. So popular was this medical officer and so successful was his work that extension after extension had to be given to cope with the huge rush of patients and the local public contributed in full for the maintenance of the dispensary. Glowing tributes were paid of its magnificent work by officials and the public of the district.

In the campaign for the prevention of blindness it is perhaps not yet realized that the problem is

largely one of the prosperity of the people and the great bulk of preventable blindness will gradually diminish as the standard of living improves. If the standards of living throughout India were the same as in Europe, then the problem of blindness would be the same as in other countries in Europe. Speaking broadly, the prevention of blindness in India is not only a medical problem but a social, economic and financial one. All of India's major problems to-day including prevention of blindness resolve themselves into or are closely connected with the education of the masses the greater number of whom are the cultivators of the soil. During the year under review many comprehensive schemes have been launched by Government for rural uplift and natural constructive work to improve the conditions of the life of the villagers. Large sums of money are being spent to provide good water supplies, improved methods in the breeding of cattle, union board dispensaries, village schools, libraries and playing grounds. The fulfilment of these schemes must lead to a general improvement in the health of the people and as a necessary corollary a diminution in the amount of preventable blindness.

The common causes of blindness in Bengal are apathy, neglect and ignorance. How are we to overcome these enemies? This must come from mass consciousness and will be an up-hill task and will not succeed unless there is a re-awakening amongst those who are now economically at the bottom. Foremost in this task is the co-operation of popular government and the people, the use of modern aids to education, such as by lectures, through the radio and the cinema before much can be done in such a vast country as India.

It is a matter of great satisfaction that the Government of Bengal has approved of the work carried out by the Association in the campaign for the prevention of blindness and has given a grant of Rs. 10,000 for the coming year.

The problem of prevention of blindness in general is so immense, it is important to face facts and realize that the remedy cannot be successful for many years and that the most important work of the Association for the prevention of blindness in Bengal is to bring home to the members of the administration and the people in general the importance of prevention of blindness and the care of eye diseases and suggest remedies for prevention and cure.

Looking back on what has been accomplished by the Association in the last eight years, considering its meagre resources, the committee have every reason to congratulate themselves on the success obtained in this noble work.

ANNUAL REPORT OF THE INSTITUTE FOR MEDICAL RESEARCH, FEDERATED MALAY STATES, FOR THE YEAR 1937. BY A. NEAVE KINGSBURY, DIRECTOR

GENERAL REVIEW

DURING the year under review there have been periods of considerable pressure on the divisions concerned with the preparation of prophylactic biological products. Towards the end of June cases of cholera among the immigrants from India were trapped at the

quarantine stations of Port Swettenham and Penang. In August infected ships from China arrived in Singapore; but in all instances the quarantine barrier was successful in preventing the spread of infection to the country at large. There were heavy demands for cholera vaccine from the quarantine stations and it was deemed desirable as a precaution to increase the stocks of that vaccine to a high level. The staff of the Division of Bacteriology responded excellently and the institute was shortly in a position to meet all reasonable requirements.

A second emergency arose in September: Singapore had been previously free from rabies for a long period, but during August an imported dog developed that disease. Other canine cases followed and it was decided to subject all dogs on the island to prophylactic vaccination. The canine population was computed to be 13,000 and between September and November thirty-eight water buffaloes were inoculated intracerebrally with 'fixed' virus for the preparation of vaccine. Certain modifications were introduced in the technique: a lymph grinding machine was utilized instead of pestle and mortar with consequent improvement in the suspension and reduced risk of bacterial contamination. Deliveries of the canine anti-rabies vaccine to the veterinary authorities in Singapore were effected according to time-table.

Vaccine lymph.—The demands rose sharply in July and continued at a high level until September—the total output was about 30 per cent higher than the annual average. The potency of a few batches prepared in 1937 proved to be somewhat low and a fresh supply of seed lymph was obtained from the Bandoeng Institute. However, the application of this seed lymph and our own 'calvine' to different areas of an animal yielded lymphs of about equal potency. It is now the practice, whenever the potency of a lymph does not exceed 1/2,000, to blend it with another batch of high potency before issue for general use.

Considerable progress is to be recorded in the various researches undertaken. The findings of Mr. E. P. Hodgkin had shown that filariasis presented a serious problem in the vicinity of the Bernam river and reports had been received of its endemicity in certain areas of Perak and Pahang. Dr. J. O. Poynton was therefore appointed as Research Student to investigate the distribution, ætiology and treatment of the disease, while Mr. Hodgkin continued his work on the entomological problems involved in transmission.

Dr. Poynton has established that infestation is widespread among the riverine population of Perak, particularly along the Perak river from Parit to within a few miles of the sea and on the Kinta and Dedap tributaries. He estimates that about 1 per cent of the population (some 50,000) have elephantiasis and that about 2 per cent more are infested. In Selangor the number of cases of elephantiasis is in the region of one hundred. Endemicity is high along the Pahang river from Labak and Triang to Kuala Pahang and cases are found on the Kuantan and Rompin rivers. The *mukims* of Pahang Tua and Pula Rusa are particularly heavily infested; about 12 per cent of the population of the former have elephantiasis or lymphangitis and some 30 per cent of the remainder have microfilaria in their blood.

Though occasional infestations with *Wuchereria bancrofti* were found, mainly in immigrants, it is believed that the local transmission of this species is relatively unimportant. The large majority of the infestations in rural areas are with *Microfilaria malayi*. The opportunities afforded by the numerous visits to *kampongs* were utilized to commence a nutritional and to extend the tuberculosis survey.

The researches undertaken by Mr. E. P. Hodgkin indicate that *Mansonia uniformis* and *M. longipalpis* are the principal local vectors of *Mf. malayi*, though *M. annulifera*, *M. annulatus* and *M. indiana* were found by experimental feeding to be susceptible to infection. From India there are reports of the control of transmission by the eradication of the water plant *Pistia stratiotes*, but in Malaya only *M. annulifera* commonly breeds in connection therewith and, as that species

seems to be relatively unimportant in transmission, the local eradication of this water plant would serve little useful purpose. *M. uniformis* breeds on the water hyacinth *Eichornia crassipes* but also in association with other water vegetation. A few larvae of *M. longipalpis* have been found with *M. uniformis* on the water hyacinth but the former species abounds in swampy jungle and the situation of its major breeding places is yet to be determined. The breeding of *M. uniformis* could probably be controlled in open swamps by drainage and proper cultivation. At present the intensity of *Mansonia* mosquitoes in some *kampongs* is such that five hundred have been taken nightly in a single trap. The infection rate, based on the present dissection results, is in the order of 1 per cent. A large number of mosquitoes have been applied to carriers of *Mf. malayi*, *W. bancrofti* and *D. immitis* in order to identify the susceptible species, and to establish, if possible, distinctive morphological characteristics that would assist in the identification of these worms in various stages of development within the vectors.

After numerous and extensive experiments with chemo-prophylaxis by Drs. J. W. Field and J. C. Niven, the Malaria Research Division is now in a position to define the minimum effective prophylactic dose of atabrin. The smallest effective quantity of atabrin for the control of clinical malaria in adults is 0.3 gramme given as a single dose at weekly intervals. The cessation of prophylaxis has, however, again been followed by an alarming and almost explosive recrudescence of malarial attacks. Under local estate conditions chemo-prophylaxis may be compared with the gauze of the old-time miner's safety lamp in a dangerous atmosphere; the flame of infection is confined but on removal an explosion seems almost inevitable.

Therapeutic tests of Totatquina II have been extended: the treatment of large series of cases of benign and malignant tertian malaria with Totatquina II and with quinine has shown that these two drugs are about equal in clinical value. It proved to be no more toxic, while its cost is about half that of quinine hydrochloride and three-quarters that of quinine sulphate. Totatquina is thus an effective anti-malarial remedy and can be safely substituted for quinine with a consequent considerable saving in expenditure.

Other preparations, 'Paludex', 'Homaline I' and 'Prontosil', have been tried but with disappointing results. Tests on guinea-pigs relative to the toxicity of atabrin have been undertaken. Injections up to sixteen times the relative human dose have been made—some after preliminary starvation to reduce glycogen—and in no case has damage to the liver, cardiac muscle or other organ been found.

The trapping of anophelines and larval surveys have been continued by the Entomological Division, working in conjunction with the Malaria Research Division. Mr. Hodgkin has taken a number of infected *A. novumbrosus* and this species must now be added to the long list of local vectors of malaria. It is a jungle swamp breeder and on the estate concerned was as important a vector as *A. umbrosus* during the year under review.

Experiments have been continued with the new oiling mixture with interesting results. Field trials by health officers and others have been undertaken and are still in progress. The few reports so far available are, with one exception, favourable. The adverse comment followed an outbreak of malaria but unfortunately detailed records of larval surveys are not available.

In the Division of Pathology, Drs. Lewthwaite and Savor have continued their researches in connection with typhus-like fevers. Strains of 'rural tropical typhus' or *tsutsugamushi* (Japanese river fever)—for these two clinical entities are now considered to be caused by the same virus—were isolated from wild rats in 1931. In the past year attempts have been made to obtain strains of 'urban' (X. 19) tropical typhus from rats taken in urban surroundings. Two strains were isolated by the inoculation of brain, etc., into

vitamin-deficient guinea-pigs and have been studied in various laboratory animals.

The search for an effective prophylactic vaccine has been continued. Wieg's vaccine, obtained from the intestines of lice infected with typhus exanthematicus, has been tested in guinea-pigs for protection against 'urban' and 'rural' (Japanese river fever) tropical typhus, but has been found to be ineffectual. Various modes of preparation of a vaccine from ascitic fluid heavily infected with *Rickettsia* have also been tried. Treatment by storage on ice and at room temperature for various periods with subsequent addition of methylene blue and exposure to radiation from a 'Pointolite' lamp has given interesting results. About one-third of the test animals had a mild reaction following vaccination. On later test inoculation of virus, the twenty-five guinea-pigs of various series that had not reacted were found to include three with complete and two with partial immunity, while the mortality rate among the vaccinated animals was only 10 per cent as compared with 95 per cent among the non-protected. Other methods of preparation—dissication, ageing, coating with yolk of egg, lanoline and olive oil—have also been attempted; up to the present, the findings, though interesting, have not been highly encouraging.

Although the use of 'Vi' antigen in the diagnosis of the enteric carrier state has not yet been explored by the Division of Bacteriology, Dr. R. Green records much work on the value of 'O' agglutinins. The analysis is based on nearly 1,500 cases; four cases of typhoid fever had been traced to an eating shop where the cook had 'O' agglutinins to between 5 and 10 units. For these purposes, however, the test has only limited value; it is useful in the diagnosis of early and symptomless cases but the presence of 'O' agglutinins and the excretion of *B. typhosus* do not necessarily coincide.

A survey of cholera in the Federated Malay States during the past thirty years is also given, including notes on bacteriological diagnosis and the present technique for vaccine production. Dr. Green invites attention to cases from which enteric and dysentery organisms, or dysentery organisms of more than one species have been isolated.

A still further expansion of some 6 per cent in the number of routine examinations is reported from the Division of Chemistry. The chief chemist invites attention to the danger of lead poisoning from the practice of the utilization of solder in the place of tin for the 'tinning' of the interior of the cheaper brass and copper cooking pots. He also sounds a note of warning with regard to the practice of storing water overnight in such pots or in soldered cans or in stone-ware jars, many of which have lead glaze: local waters are often plumbosolvent.

The Ipoh Branch Laboratory experienced a very busy year for the number of routine specimens totalled nearly 30,000—an increase of some 30 per cent—this pressure necessitated the deferring of certain investigations that had been planned. A little progress was made in the tuberculosis survey, and 1,670 Perak children have now been subjected to the tuberculin test. With some thousand urban children, positive results have been encountered in 53 per cent of 516 Chinese, 33 per cent of 470 Malays, 18 per cent of 68 Tamils, and 23 per cent of 51 Sikhs of various age groups.

In connection with a report on laboratory examinations following a health survey of a group of Sen-Oi Sakai, Dr. Nevin also includes some interesting sociological observations. Blood films were taken in the day-time for a malaria survey and 10 per cent of them were found to contain microfilaria. An almost universally high eosinophilia led to a search for helminth ova and 70 per cent of the group proved to be infested with *Ascaris lumbricoides*, 26 per cent with *Ankylostome duodenale* and 14 per cent with *Trichuris trichiura*.

Progress has been made with the rat virus enquiry. Herd experiments with *P. aviseptica*, *P. cuniculiseptica*, *P. muriseptica*, *S. enteritidis*, Medan, Liverpool and

Ratin, and infectious ectromelia have confirmed that there is little possibility of precipitating an epidemic among local rats by means of these agents. However, when a selected strain of *S. enteritidis*, cultured in milk, was fed to batches of rats the subsequent death rate in two separate experiments were 87 and 80 per cent. This strain is thus effective for rat extermination, but it is pathogenic to man and consequently its employment is inadvisable wherever there may be possibility of contamination of food or of water supplies. Certain commercial rat 'viruses' and poisons have been examined; none of the viruses and few of the poisons have proved to be really effective.

UNIVERSITY OF CALCUTTA. EIGHTEENTH ANNUAL REPORT OF THE STUDENTS' WELFARE COMMITTEE FOR 1937-38

The medical board attached to the students' welfare committee visited the following institutions during the year 1937:—

- (1) Hindu Academy,
- (2) Bowbazar High School,
- (3) Mitra Institution, Bhowanipur Branch,
- (4) South Suburban School (Main), Bhowanipur,
- (5) Ashutosh College, Bhowanipur, and examined the health of 2,777 students (college students 354 and school students 2,423). This brings the total number of students examined to 37,043.

Each student examined was supplied with a report on the state of his health. A copy of the report was forwarded to the institution concerned for information and a third copy was preserved in the department for reference and investigation. This new arrangement, introduced during the year under consideration, has added considerably to the routine work of the office. But the additional work will be amply repaid if it induces the student to take a greater interest in his health and to utilize the facilities offered by the committee for health preservation to a larger extent. In addition, separate reports on the state of health of the students examined were sent to the institution concerned shortly after the completion of the medical examination. These reports contained a list of students found to be suffering from any disease or defects together with the recommendation suggested for rectifying them.

The proportion of students suffering from diseases or defects requiring immediate attention was 41.6 per cent as compared with 53.6 per cent for 1936 and 63 per cent for 1935. This is the lowest percentage as yet obtained and indicates that there has been a perceptible improvement in the health of the students. The following table gives an analysis of the findings of medical examination:—

TABLE I

Name of diseases	Figures for college students given in percentage (number of students 354)	Figures for school students given in percentage (number of students 2,423)
Defective vision	38.13	30.14
Malnutrition ..	23.44	31.11
Enlarged tonsils	1.69	10.94
Caries (dental)	7.06	20.98
Skin diseases ..	1.97	3.96
Lung diseases ..	1.34	2.02
Enlarged liver ..	9.28	1.03
Enlarged spleen	0.56	0.74
Pyorrhœa ..	1.12	0.45
Heart disease	2.80

There has been a decline in the incidence of diseases on all heads except affections of the lungs, and heart and of pyorrhœa. The incidence of malnutrition has come down this year to 23.4 per cent among college students and 31.1 per cent among the school students, i.e., much below the usual figures found in other years. The decline in the incidence of malnutrition indicates that the students and their guardians are taking a

greater interest in the preservation of health. The incidence of students requiring immediate medical attention has declined from 66 per cent for the triennium 1920-22 to 41 per cent for 1937. This general improvement of students' health seems to indicate that the work of the committee has begun to yield the results hoped for when it first began its work in 1921. The effect of the last recrudescence of epidemic dropsy in Calcutta is still distinctly seen in the higher incidence of affections of the heart among both groups of students.

REPORT ON THE STATE OF PUBLIC HEALTH IN BURMA DURING 1937

The major epidemic diseases in Burma are cholera, plague and smallpox. All the three are preventable. Under the present system responsibility for efficient measures for the suppression of epidemic diseases rests with the local bodies concerned, i.e., municipalities and district councils. The occurrence of any of these diseases in epidemic form is a reflection on the local administration concerned. In past years ignorance and apathy on the part of the public have made preventive measures difficult, but signs are not wanting that there is a slow but steady change and that, if those in authority take the lead, public response does follow.

Cholera.—During the year from the whole of Burma there were reported a total of 3,491 deaths from this disease. This gives a provincial death rate of 0.29, which is a rise of 0.21 over the previous year's rate and 0.13 over the five-year mean.

Plague.—There was a total of 1,526 deaths from this disease during the year. The provincial rate for the year under review is 0.13 which is 0.06 below the previous year's rate and 0.01 below the five-year mean. Arakan Division was entirely free from this disease as usual, and seven other districts reported no mortality from it during the year. The most important town that is affected by this disease is Mandalay in which it has been occurring for many years in bi-annual epidemics. In 1936 there were 624 deaths from this disease and in the year under review 210.

Smallpox.—During the year under review the total number of deaths from this disease was 1,370, of which 138 occurred in children under one year of age and 281 in children over one year and under 10 years of age. The provincial rate is 0.11 which is the same as last year and is 0.03 below the five-year mean. The disease was most prevalent during the period January to May and gradually declined towards the close of the year. Mortality was reported from every district except Kyaukse and Yamethin.

MEASURES DIRECTED AGAINST EPIDEMIC DISEASES

Education is carried out by means of cinema shows, magic lantern demonstrations, lectures and the distribution of leaflets which work is undertaken by the Hygiene Publicity Bureau and the district cadre of the Public Health Department.

Enteric fever.—In many countries the incidence of this disease is taken as the sanitary index by which the efficiency of public health measures in a town can be judged. This is not possible in Burma as we have no true record of its incidence owing to the lack of accurate bacteriological investigation of cases, therefore, there are no accurate statistical data from which to draw conclusions by comparison.

Dysentery and diarrhoea.—The total number of deaths from this disease reported during the year was 6,987. This gives a provincial rate of 0.58 which is higher than last year and 0.13 in excess of the five-year mean. As in previous years the highest number of deaths from this condition was reported in the month of July when 1,137 deaths were recorded.

Respiratory diseases.—A total of 13,907 deaths from respiratory diseases was reported during the year which is a slight increase over last year though the rate, 1.15, remains the same. It is considered that statistics with regard to these conditions are fairly accurate for urban areas but are, inevitably, inaccurate for rural areas.

Beri-beri.—The incidence of this disease in districts can only be roughly gauged from the reports of district health officers and from requests for assistance to deal with it made on this department from large employers of labour. Rangoon had 86 deaths during the year under review which is the same as in the previous year though the number of cases 174 is slightly lower than that of 1936. Bassein reported 17 deaths while from towns from the rest of the Irrawaddy Division there were a total of 20 deaths reported. Mergui reported 25 deaths which is a very considerable increase over the previous year's figure of 21. As in previous years this disease continued to appear mostly in members of the Indian community.

Cerebrospinal fever.—This is the first year in which this disease has been reported in epidemic form in Burma. It appears to have started in a village near Kalembo in Upper Chindwin District, thence it spread to Haka Subdivision of the Chin Hills District. The district health officers and the civil sub-assistant surgeons concerned made every effort to cope with this problem. It presented great difficulties as the area is very wild and inaccessible and the people are very ignorant and superstitious. Reports of deaths were often received many days later so that the collection of accurate information as to what really had happened was very difficult. At first this department inclined to the view that it was influenza coupled with malaria and not cerebrospinal fever. However the care with which the medical officers concerned recorded observed and hearsay symptoms eventually established the diagnosis beyond doubt.

Malaria.—Malaria kills more people and does more damage to physical, social and economic welfare in rural portions of Far Eastern countries (especially in the tropics and sub-tropics) than any other disease. Yet malaria is insidious, and except in epidemic form, it does not manifest itself with dramatic power sufficient to attract attention and funds commensurate with its ability to destroy health and prosperity. The above remark made by the Malaria Committee of the Inter-Governmental Conference of Far Eastern Countries on Rural Hygiene, held in Java in August 1937, is, unfortunately, as true of Burma as of other countries of the East and the Far East.

Veneral diseases.—The exact extent of this problem is not known, but that it is an important major problem is the opinion of all civil surgeons and district health officers. Most unfortunately it is not clearly appreciated in this country that the evil effects of these diseases do not terminate with their manifestations in those afflicted but are liable to recur in the generations yet to come. Seventy-three thousand eight hundred and ninety-eight persons were treated for venereal diseases during the year under report, of whom 34,381 were suffering from syphilis and 26,628 from gonococcal infection, the remainder having other diseases of venereal origin. The number of deaths that took place in hospitals from syphilis and gonorrhoea are 55 and 9 respectively, but in those towns where deaths from these two conditions are registered, the corresponding figures are 322 and 15. The very grave disparity between these two sets of figures shows clearly that the number of patients treated in hospitals is a small percentage of those actually suffering from these diseases. In Rangoon general hospital out of 788 post-mortem examinations carried out during the year, signs of syphilis were detected in 123, while venereal infection was traced in 467 cases out of 2,880 admissions into the four maternity and infant welfare shelters in Rangoon.

Leprosy.—Three hundred and fifty-seven deaths were reported from this disease during the year under report. There is, however, no doubt that it is a much more serious problem than would appear from these figures. The fact is that mortality from leprosy is recorded only in towns, and therefore we have no real information as to its incidence. The problem is not easy and it is not believed that the extension of compulsory notification would necessarily yield the information desired. Compulsory notification of this disease, which at present is only in force in Mōnywa and Maymyo,

might result in even more evasion than exists at present with voluntary measures.

Tuberculosis.—It is impossible to state with any accuracy how many die each year in Burma from tuberculosis as the figures as a whole are not sufficiently complete and undoubtedly many deaths from this disease are undiagnosed and unreported. From such figures as are available there is little doubt but that this disease presents a problem of ever-growing importance to the people of Burma. The history of tuberculosis shows that a heavy incidence may be expected where an agricultural population turns towards city and factory life. This factor is not present to any marked degree in Burma so it is reasonable to hope that energetic preventive and curative measures should meet with success in reducing the total morbidity and mortality from this disease. If we could achieve careful isolation and treatment of the individual case coupled with a suitable regime of home life for contacts we should have gone far towards eliminating this disease. This is axiomatic in any country but there are reasons to suggest that, though difficult or impossible to accomplish elsewhere, it could be managed in Burma.

ANNUAL REPORT OF THE SANITARY BOARD, BENGAL, FOR THE YEAR 1937

IMPROVEMENT in the financial condition of the province enabled Government to revert to the policy of making grants towards water-supply, drainage and sewerage schemes. Although, in the absence of any matured schemes, no part of the provision made for this purpose was actually availed of by local bodies during the year, the revival of the grants resulted in definite encouragement to local bodies to undertake sanitary engineering schemes.

The total expenditure on water-supply, drainage and sewerage schemes recorded a further rise during the year. The expenditure on waterworks amounted to Rs. 7,50,326 and that on sewerage to Rs. 1,52,027 as against Rs. 5,70,472 and Rs. 56,649 respectively in the previous year.

Sketch projects for schemes estimated to cost Rs. 28,04,250, detailed projects to the estimated value of Rs. 12,25,298, and detailed estimates and plans for miscellaneous works amounting to Rs. 51,268 were drawn up during the year under review. Investigation and preparation of sanitary engineering schemes may thus be said to have made good progress.

The chief engineer, public health department, reports that all the six municipal towns which have recently constructed waterworks have adopted the decentralized storage system.

In order that all works of water-supply for domestic purposes as well as all sanitary and drainage projects in the rural areas may receive the necessary amount of expert supervision, the chief engineer has been appointed inspector of local works for this purpose. All tube-well projects proposed to be financed from the Government of India grants for rural uplift were, under orders of Government, referred to the chief engineer for previous approval. After examining the schemes, the chief engineer gave suitable instructions for sinking and maintenance in each case.

In his report the chief engineer has alluded to the advance which has been made in the matter of converting indifferent tube-well water into first class drinking water by treating the water according to a number of comparatively inexpensive processes.

The department continued to render valuable assistance to the municipal bodies and other local authorities by way of inspection, advice and supervision and the local bodies, on the whole, readily co-operated with the department.

The sanitary board, held four meetings during the year and examined various engineering and public health schemes before forwarding them to Government. The board also reviewed the inspection reports of departmental officers and gave useful advice. A sub-committee was appointed by the board during the year under review to investigate whether the introduction of water-supply in towns without provision of effective drainage had led to an increase in malaria and to consider what steps should be taken if the data obtained indicated any appreciable rise in the incidence of malaria in such cases.

Service Notes

APPOINTMENTS AND TRANSFERS

COLONEL D. F. MURPHY, M.C., to be Officiating A. D. M. S., Deccan District. Dated 24th January, 1939.

Colonel W. A. M. Jack, O.B.E., to be Officiating A. D. M. S., Rawalpindi District. Dated 5th January, 1939.

Lieutenant-Colonel A. N. Sharma to be O. C., No. 7 Field Ambulance, Razmak. Dated 15th February, 1939.

Lieutenant-Colonel W. C. Spackman returned from leave and resumed charge of the duties of Professor of Midwifery and Gynaecology, Grant Medical College, and Senior Specialist in Obstetrics with Gynaecology, Bai Motlibai and Sir D. M. Petit Hospitals, Bombay, with effect from the forenoon of the 3rd February, 1939.

Lieutenant-Colonel J. B. Hance, C.I.E., O.B.E., an Agency Surgeon, on return from leave, resumed charge of his appointment of Residency Surgeon, Mysore, with effect from the forenoon of the 1st January, 1939.

Lieutenant-Colonel A. C. Craighead to be A. D. P., Southern Command. Dated 26th December, 1938.

Lieutenant-Colonel F. Phelan to be Officiating O. C., I. M. H., Poona. Dated 14th January, 1939.

Lieutenant-Colonel B. S. Dhondy to be Officiating O. C., I. M. H., Lucknow. Dated 2nd January, 1939.

Lieutenant-Colonel J. G. McCann to be Officiating O. C., I. M. H., Shillong. Dated 18th January, 1939.

Lieutenant-Colonel H. R. Cursetji to be Officiating O. C., I. M. H., Secunderabad. Dated 24th January, 1939.

Major G. Milne is appointed to officiate as an Agency Surgeon, with effect from the afternoon of the 18th January, 1939, and is posted to the North-West Frontier Province.

Major S. D. Gupta to be Officiating Specialist in Radiology, Lucknow District. Dated 18th January, 1939.

Major M. H. Wace to be Officiating O. C., Labour Camp Hospital, Quetta. Dated 17th January, 1939.

Major A. M. Chaudhuri to be Surgical Specialist, Sialkot. Dated 7th December, 1938.

Transferred to Civil

Major G. Milne to North-West Frontier Province on 18th January, 1939.

Captain C. J. Hassett to North-West Frontier Province on 3rd January, 1939.

Captain A. B. Guild to civil U. P., on 14th January, 1939.

Captain S. Shone to civil Madras on 18th January, 1939.

Captain F. J. Doherty, D.S.O., to be O. C., I. M. H., Mardan. Dated 18th January, 1939.

Captain W. J. Virgin to be Staff Surgeon, Dehra Dun. Dated 18th January, 1939.

Captain R. J. Henderson to be Officer in charge, Brigade Laboratory, Abbottabad. Dated 28th December, 1938.

Captain B. M. Wheeler to be Officer in charge, Brigade Laboratory, Karachi. Dated 2nd January, 1939.

Captain M. H. Shah, Additional Civil Surgeon, Delhi, is appointed to officiate as Chief Medical Officer, Delhi, with effect from the 27th April, 1939, *vice* Lieutenant-Colonel R. H. Candy, C.I.E., granted leave.

Captain A. B. Guild, whose services have been placed temporarily at the disposal of the United Provinces Government for Civil employ, has been posted as Civil Surgeon, Gorakhpur.

On return from combined leave *ex-India*, from Aurangabad, Captain D. H. Waldron joined I. M. H., Quetta, on the 15th February, 1939.

Captain J. H. Gorman to Bombay Central Government as a leave reserve officer, on the 6th February, 1939.

Captain G. E. S. Stewart to be Officiating Officer in charge, I. H. C. Records, Kirkee, in addition to his normal duties. Dated 13th February, 1939.

Captain D. R. Sharma to be Officiating O. C., C. I. M. H., Mir Ali. Dated 25th February, 1939.

The undermentioned Officers reported for training at the Indian Military Hospital, Rawalpindi, on appointment to short service commissions in the I. M. S.:—

Lieutenant N. D. P. Karani.

Lieutenant Dipak Bhatia.

Lieutenant Indrajit Singh.

The undermentioned Officers reported for training at the Indian Military Hospital, Lucknow, on appointment to short service commissions in the I. M. S.:—

Lieutenant N. Jungalwalla.

Lieutenant D. D. Verma.

The undermentioned I. M. S. Officers arrived at Karachi per H. T. 'Laucashire' on 10th January, 1939, on first appointment:—

Captain O. Walker.

Lieutenant J. M. M. Drew.

Lieutenant E. L. Wilson.

Lieutenant M. D. Black.

Lieutenant H. C. Rogers.

Lieutenant J. E. Ennis.

Lieutenant I. D. Sutherland.

Lieutenant S. H. Heard.

Lieutenant H. R. Loughran.

Lieutenant J. J. Woodward.

Lieutenant G. J. H. Maud.

Lieutenant J. A. Anderson.

Lieutenant P. M. Kirkwood.

Lieutenant D. J. P. Spillane.

To be Captain (on probation)

20th December, 1938

Oliver Walker with seniority in the rank of Lieutenant (on probation) from 11th November, 1936, and as Captain (on probation) 11th November, 1937. The period 22nd October, 1937 to 29th November, 1938 (inclusive), to count for purposes of promotion and increments of pay, but not for retired pay or gratuity.

To be Lieutenants (on probation)

1st January, 1939

Cedric Culy Harvey, with seniority 1st July, 1937.
Robert John McGill, with seniority 1st July, 1937.
Lionel Edward Elkerton, with seniority 1st January, 1938.

Austen Maxwell Best, with seniority 1st January, 1938.

John Lightbody, with seniority 1st January, 1938.
Herbert Fitzroy Townsend MacFetridge, with seniority 1st January, 1938.

David Frank Eastcott, with seniority 1st July, 1938.
Harry Rees (seconded).

The undermentioned Officers are restored to the establishment:—

Lieutenant (on probation) J. A. M. Cameron, 1st January, 1939, with seniority from 1st July, 1937.

Lieutenant (on probation) L. H. Cooper, 1st January, 1939, with seniority from 1st August, 1938.

Lieutenant (on probation) W. S. Hacon is restored to the establishment, 1st January, 1939. This Officer's seniority is antedated to the 11th July, 1938.

LEAVE

Colonel A. F. Babonau, C.I.E., O.B.E., V.H.S., A.D.M.S., Deccan District, proceeded on 4 months and 28 days' combined leave *ex-India* pending retirement on 24th January, 1939.

Lieutenant-Colonel A. D. Loganadan is granted combined leave for 12 months.

Lieutenant-Colonel R. H. Candy, C.I.E., Chief Medical Officer, Delhi, is granted, with effect from the 27th April, 1939, combined leave for 4 months.

Lieutenant-Colonel R. Sen, O. C., I. M. H., Allahabad, proceeded on 9 months' combined leave *ex-India* on the 6th February, 1939.

Lieutenant-Colonel A. V. Lopes, Officer in charge, I. H. C. Records, Kirkee, proceeded on 12 months' combined leave *ex-India* on the 7th February, 1939.

Lieutenant-Colonel M. D. A. Kureishi, O. C., I. M. H., Poona, proceeded on 9 months' combined leave *ex-India* on 14th January, 1939.

Lieutenant-Colonel D. V. O'Malley, O.B.E., O. C., I. M. H., Shillong, proceeded on 12 months' combined leave *ex-India* on 18th January, 1939.

Major R. K. Tandon, O. C., Labour Camp Hospital, Quetta, proceeded on 8 months' combined leave *ex-India* on 17th January, 1939.

Major B. N. Hajra, C. I. M. H., Wana, proceeded on 8 months' combined leave in India on 25th January, 1939.

Major W. J. Shipsey, I. M. H., Shillong, proceeded on 8 months' combined leave *ex-India* on the 5th February, 1939.

Major A. J. C. Culhane, Civil Surgeon, Naini Tal, proceeded on 1 year's Medical leave from 22nd January, 1939.

Captain F. W. Whiteman, I. M. H., Alipore, proceeded on 12 months' combined leave *ex-India* on the 10th February, 1939.

Captain C. W. A. Searle, Officiating O. C., C. I. M. H., Mir Ali, proceeded on 8 months' combined leave *ex-India* on the 25th February, 1939.

Captain R. de Soldenhoff proceeded on combined leave for 8 months, with effect from the forenoon of 11th February, 1939.

PROMOTIONS

Majors to be Lieutenant-Colonels

P. N. Lahiri. Dated 28th January, 1939.

M. K. Kelavkar. Dated 18th February, 1939.

Captains to be Majors

W. Happer. Dated 2nd February, 1939.

H. T. McWilliams. Dated 4th February, 1939.

H. J. Curran. Dated 4th February, 1939.

W. P. Lappin. Dated 4th February, 1939.

B. J. Griffiths. Dated 4th February, 1939.

J. H. Gorman. Dated 4th February, 1939.

F. H. A. L. Davidson. Dated 4th February, 1939.

M. H. Shah. Dated 10th February, 1939.

Lieutenants (on probation) to be Captains (on probation)

J. W. Lillice. Dated 1st January, 1939.

E. L. Wilson. Dated 10th January, 1939, with seniority from 31st August, 1938.

H. C. Rogers. Dated 10th January, 1939, with seniority from 1st September, 1938.

J. M. Drew. Dated 10th January, 1939, with seniority from 1st November, 1938.

RETIREMENTS

Lieutenant-Colonel F. Griffith retired on 14th January, 1939.

Major R. D. Alexander retired on 3rd January, 1939.

RESIGNATION

Captain P. B. Cusack resigned from the service on the 10th February, 1939.

might result in even more evasion than exists at present with voluntary measures.

Tuberculosis.—It is impossible to state with any accuracy how many die each year in Burma from tuberculosis as the figures as a whole are not sufficiently complete and undoubtedly many deaths from this disease are undiagnosed and unreported. From such figures as are available there is little doubt but that this disease presents a problem of ever-growing importance to the people of Burma. The history of tuberculosis shows that a heavy incidence may be expected where an agricultural population turns towards city and factory life. This factor is not present to any marked degree in Burma so it is reasonable to hope that energetic preventive and curative measures should meet with success in reducing the total morbidity and mortality from this disease. If we could achieve careful isolation and treatment of the individual case coupled with a suitable regime of home life for contacts we should have gone far towards eliminating this disease. This is axiomatic in any country but there are reasons to suggest that, though difficult or impossible to accomplish elsewhere, it could be managed in Burma.

ANNUAL REPORT OF THE SANITARY BOARD, BENGAL, FOR THE YEAR 1937

IMPROVEMENT in the financial condition of the province enabled Government to revert to the policy of making grants towards water-supply, drainage and sewerage schemes. Although, in the absence of any matured schemes, no part of the provision made for this purpose was actually availed of by local bodies during the year, the revival of the grants resulted in definite encouragement to local bodies to undertake sanitary engineering schemes.

The total expenditure on water-supply, drainage and sewerage schemes recorded a further rise during the year. The expenditure on waterworks amounted to Rs. 7,50,326 and that on sewerage to Rs. 1,52,027 as against Rs. 5,70,472 and Rs. 56,649 respectively in the previous year.

Sketch projects for schemes estimated to cost Rs. 28,04,250, detailed projects to the estimated value of Rs. 12,25,298, and detailed estimates and plans for miscellaneous works amounting to Rs. 51,268 were drawn up during the year under review. Investigation and preparation of sanitary engineering schemes may thus be said to have made good progress.

The chief engineer, public health department, reports that all the six municipal towns which have recently constructed waterworks have adopted the decentralized storage system.

In order that all works of water-supply for domestic purposes as well as all sanitary and drainage projects in the rural areas may receive the necessary amount of expert supervision, the chief engineer has been appointed inspector of local works for this purpose. All tube-well projects proposed to be financed from the Government of India grants for rural uplift were, under orders of Government, referred to the chief engineer for previous approval. After examining the schemes, the chief engineer gave suitable instructions for sinking and maintenance in each case.

In his report the chief engineer has alluded to the advance which has been made in the matter of converting indifferent tube-well water into first class drinking water by treating the water according to a number of comparatively inexpensive processes.

The department continued to render valuable assistance to the municipal bodies and other local authorities by way of inspection, advice and supervision and the local bodies, on the whole, readily co-operated with the department.

The sanitary board, held four meetings during the year and examined various engineering and public health schemes before forwarding them to Government. The board also reviewed the inspection reports of departmental officers and gave useful advice. A sub-committee was appointed by the board during the year under review to investigate whether the introduction of water-supply in towns without provision of effective drainage had led to an increase in malaria and to consider what steps should be taken if the data obtained indicated any appreciable rise in the incidence of malaria in such cases.

Service Notes

APPOINTMENTS AND TRANSFERS

COLONEL D. F. MURPHY, M.C., to be Officiating A. D. M. S., Deccan District. Dated 24th January, 1939.

Colonel W. A. M. Jack, O.B.E., to be Officiating A. D. M. S., Rawalpindi District. Dated 5th January, 1939.

Lieutenant-Colonel A. N. Sharma to be O. C., No. 7 Field Ambulance, Razmak. Dated 15th February, 1939.

Lieutenant-Colonel W. C. Spackman returned from leave and resumed charge of the duties of Professor of Midwifery and Gynaecology, Grant Medical College, and Senior Specialist in Obstetrics with Gynaecology, Bai Motlibai and Sir D. M. Petit Hospitals, Bombay, with effect from the forenoon of the 3rd February, 1939.

Lieutenant-Colonel J. B. Hance, C.I.E., O.B.E., an Agency Surgeon, on return from leave, resumed charge of his appointment of Residency Surgeon, Mysore, with effect from the forenoon of the 1st January, 1939.

Lieutenant-Colonel A. C. Craighead to be A. D. P., Southern Command. Dated 26th December, 1938.

Lieutenant-Colonel F. Phelan to be Officiating O. C., I. M. H., Poona. Dated 14th January, 1939.

Lieutenant-Colonel B. S. Dhondy to be Officiating O. C., I. M. H., Lucknow. Dated 2nd January, 1939.

Lieutenant-Colonel J. G. McCann to be Officiating O. C., I. M. H., Shillong. Dated 18th January, 1939.

Lieutenant-Colonel H. R. Cursetji to be Officiating O. C., I. M. H., Secunderabad. Dated 24th January, 1939.

Major G. Milne is appointed to officiate as an Agency Surgeon, with effect from the afternoon of the 18th January, 1939, and is posted to the North-West Frontier Province.

Major S. D. Gupta to be Officiating Specialist in Radiology, Lucknow District. Dated 18th January, 1939.

Major M. H. Wace to be Officiating O. C., Labour Camp Hospital, Quetta. Dated 17th January, 1939.

Major A. M. Chaudhuri to be Surgical Specialist, Sialkot. Dated 7th December, 1938.

Transferred to Civil

Major G. Milne to North-West Frontier Province on 18th January, 1939.

Captain C. J. Hassett to North-West Frontier Province on 3rd January, 1939.

Captain A. B. Guild to civil U. P., on 14th January, 1939.

Captain S. Shone to civil Madras on 18th January, 1939.

Captain F. J. Doherty, D.S.O., to be O. C., I. M. H., Mardan. Dated 18th January, 1939.

Captain W. J. Virgin to be Staff Surgeon, Dehra Dun. Dated 18th January, 1939.

Captain R. J. Henderson to be Officer in charge, Brigade Laboratory, Abbottabad. Dated 28th December, 1938.

Captain B. M. Wheeler to be Officer in charge, Brigade Laboratory, Karachi. Dated 2nd January, 1939.

Captain M. H. Shah, Additional Civil Surgeon, Delhi, is appointed to officiate as Chief Medical Officer, Delhi, with effect from the 27th April, 1939, vice Lieutenant-Colonel R. H. Candy, c.i.e., granted leave.

Captain A. B. Guild, whose services have been placed temporarily at the disposal of the United Provinces Government for Civil employ, has been posted as Civil Surgeon, Gorakhpur.

On return from combined leave *ex-India*, from Aurangabad, Captain D. H. Waldron joined I. M. II., Quetta, on the 15th February, 1939.

Captain J. H. Gorman to Bombay Central Government as a leave reserve officer, on the 6th February, 1939.

Captain G. E. S. Stewart to be Officiating Officer in charge, I. H. C. Records, Kirkee, in addition to his normal duties. Dated 13th February, 1939.

Captain D. R. Sharma to be Officiating O. C., C. I. M. H., Mir Ali. Dated 25th February, 1939.

The undermentioned Officers reported for training at the Indian Military Hospital, Rawalpindi, on appointment to short service commissions in the I. M. S.:—

Lieutenant N. D. P. Karani.

Lieutenant Dipak Bhatia.

Lieutenant Indrajit Singh.

The undermentioned Officers reported for training at the Indian Military Hospital, Lucknow, on appointment to short service commissions in the I. M. S.:—

Lieutenant N. Jungalwalla.

Lieutenant D. D. Verma.

The undermentioned I. M. S. Officers arrived at Karachi per H. T. 'Lancashire' on 10th January, 1939, on first appointment:—

Captain O. Walker.

Lieutenant J. M. M. Drew.

Lieutenant E. L. Wilson.

Lieutenant M. D. Black.

Lieutenant H. C. Rogers.

Lieutenant J. E. Ennis.

Lieutenant I. D. Sutherland.

Lieutenant S. H. Heard.

Lieutenant H. R. Loughran.

Lieutenant J. J. Woodward.

Lieutenant G. J. H. Maud.

Lieutenant J. A. Anderson.

Lieutenant P. M. Kirkwood.

Lieutenant D. J. P. Spillane.

To be Captain (on probation)

20th December, 1938

Oliver Walker with seniority in the rank of Lieutenant (on probation) from 11th November, 1936, and as Captain (on probation) 11th November, 1937. The period 22nd October, 1937 to 29th November, 1938 (inclusive), to count for purposes of promotion and increments of pay, but not for retired pay or gratuity.

To be Lieutenants (on probation)

1st January, 1939

Cedrie Culy Harvey, with seniority 1st July, 1937.

Robert John McGill, with seniority 1st July, 1937.

Lionel Edward Elkerton, with seniority 1st January, 1938.

Austen Maxwell Best, with seniority 1st January, 1938.

John Lightbody, with seniority 1st January, 1938.

Herbert Fitzroy Townsend MacFetridge, with seniority 1st January, 1938.

David Frank Eastcott, with seniority 1st July, 1938.

Harry Rees (seconded).

The undermentioned Officers are restored to the establishment:—

Lieutenant (on probation) J. A. M. Cameron, 1st January, 1939, with seniority from 1st July, 1937.

Lieutenant (on probation) L. H. Cooper, 1st January, 1939, with seniority from 1st August, 1938.

Lieutenant (on probation) W. S. Hacon is restored to the establishment, 1st January, 1939. This Officer's seniority is antedated to the 11th July, 1938.

LEAVE

Colonel A. F. Babonau, c.i.e., o.b.e., v.h.s., A.D.M.S., Deccan District, proceeded on 4 months and 28 days' combined leave *ex-India* pending retirement on 24th January, 1939.

Lieutenant-Colonel A. D. Loganadan is granted combined leave for 12 months.

Lieutenant-Colonel R. H. Candy, c.i.e., Chief Medical Officer, Delhi, is granted, with effect from the 27th April, 1939, combined leave for 4 months.

Lieutenant-Colonel R. Sen, O. C., I. M. H., Allahabad, proceeded on 9 months' combined leave *ex-India* on the 6th February, 1939.

Lieutenant-Colonel A. V. Lopes, Officer in charge, I. H. C. Records, Kirkee, proceeded on 12 months' combined leave *ex-India* on the 7th February, 1939.

Lieutenant-Colonel M. D. A. Kureishi, O. C., I. M. H., Poona, proceeded on 9 months' combined leave *ex-India* on 14th January, 1939.

Lieutenant-Colonel D. V. O'Malley, o.b.e., O. C., I. M. II., Shillong, proceeded on 12 months' combined leave *ex-India* on 18th January, 1939.

Major R. K. Tandon, O. C., Labour Camp Hospital, Quetta, proceeded on 8 months' combined leave *ex-India* on 17th January, 1939.

Major B. N. Hajra, C. I. M. H., Wana, proceeded on 8 months' combined leave in India on 25th January, 1939.

Major W. J. Shipsey, I. M. H., Shillong, proceeded on 8 months' combined leave *ex-India* on the 5th February, 1939.

Major A. J. C. Culhane, Civil Surgeon, Naini Tal, proceeded on 1 year's Medical leave from 22nd January, 1939.

Captain F. W. Whiteman, I. M. H., Alipore, proceeded on 12 months' combined leave *ex-India* on the 10th February, 1939.

Captain C. W. A. Searle, Officiating O. C., C. I. M. H., Mir Ali, proceeded on 8 months' combined leave *ex-India* on the 25th February, 1939.

Captain R. de Soldenhoff proceeded on combined leave for 8 months, with effect from the forenoon of 11th February, 1939.

PROMOTIONS

Majors to be Lieutenant-Colonels

P. N. Lahiri. Dated 28th January, 1939.

M. K. Kelavkar. Dated 18th February, 1939.

Captains to be Majors

W. Happer. Dated 2nd February, 1939.

H. T. McWilliams. Dated 4th February, 1939.

H. J. Curran. Dated 4th February, 1939.

W. P. Lappin. Dated 4th February, 1939.

B. J. Griffiths. Dated 4th February, 1939.

J. H. Gorman. Dated 4th February, 1939.

F. H. A. L. Davidson. Dated 4th February, 1939.

M. H. Shah. Dated 10th February, 1939.

Lieutenants (on probation) to be Captains (on probation)

J. W. Lillice. Dated 1st January, 1939.

E. L. Wilson. Dated 10th January, 1939, with seniority from 31st August, 1938.

H. C. Rogers. Dated 10th January, 1939, with seniority from 1st September, 1938.

J. M. Drew. Dated 10th January, 1939, with seniority from 1st November, 1938.

RETIREMENTS

Lieutenant-Colonel F. Griffith retired on 14th January, 1939.

Major R. D. Alexander retired on 3rd January, 1939.

RESIGNATION

Captain P. B. Cusack resigned from the service on the 10th February, 1939.

Notes

BOVRIL FOR EMERGENCIES

IN September last year, Bovril Ltd. and its associates had in England about two years' normal sales supply. At a time of crisis, however, it was obviously more difficult to cope with last-minute demands. Those, therefore, who were wise would see to it that they obtained extra supplies before a time of crisis and that they maintained these extra supplies in their store cupboards. Actually to-day the company's supplies were even larger than they were in September last year and the company was therefore capable of providing extra supplies, without dislocating normal distribution, for all those wise people who wished to have stocks of Bovril in store.

The company would endeavour to see to it that the supplies of Bovril for ordinary everyday use as a beverage, for cooking, and for use in illness or convalescence, were sufficient, and they would actually be helped in this if people who could afford to lay in supplies laid them in and maintained them as a matter of course, without waiting for an emergency to arise.

In spite of the disturbed conditions of the world's trade, the Bovril export trade showed an increase over the previous year.

The Duke of Atholl (Vice-chairman), said: The world was in a terrible state, morally, financially, and commercially, but the company's product had won right through at every point during these difficult times because it was a genuine article, it was easy to handle, it kept well, and incidentally, he supposed, it was about the greatest comfort in times of adversity. It was very gratifying to know that their product was well received all over the world.

VERITOL

VERITOL, recently placed on the market by the Knoll Chemical Works, has an energetic pressor action; it is said that in circulatory depression it effects a long-enduring restitution of the haemodynamic equilibrium. Its sphere of attack is primarily in the periphery; by redistribution of the blood pooled in the depots the amount of circulating blood is increased, but without any disadvantageous acceleration of the heart-rate, seeing that the increase in the minute volume is for the most part due to an improved cardiac output. Since the onset of the Veritol action is only gradual, no sudden extra strain is thrown on the heart. Other advantages over adrenalin claimed are the much longer duration of effect and the increased perfusion of the coronary vessels, the latter achieved without any intensification of the metabolic function. The superiority of Veritol over ephedrine lies in the fact that even repeated doses produce no deterioration of the cardiac function. It is evident that the substance also leads to some arterial constriction which does not, however, throttle functionally important circulatory sections, like that of the kidney, for instance. In contrast with other bodies of the adrenalin-ephedrine series, Veritol has been found to stimulate diuresis. The product renders valuable services in primary circulatory depression associated with a seriously lowered blood-pressure as the result of loss of blood, retention of blood in the periphery through peripheral vascular paralysis (operations, toxic damage, prolonged states of poisoning, etc.); also in depression of the vascular tonus. The reliable pressor action of oral doses of Veritol renders this form of application especially suitable for fighting protracted states of hypotonia (child-bed, convalescence).

LAROSTIDIN AND PEPTIC ULCER

DR. M. M. BENEDICT writing in the *Military Surgeon* on a study in the treatment of peptic ulcer draws the following conclusion:—

'The parenteral administration of histidine monohydrochloride in 132 cases of gastro-intestinal disorders.

112 of which were peptic ulcer, was followed by rapid remission of clinical symptoms and radiologic evidence of improvement.

Regulation of the diet and the mode of living need not be as strict as with other types of treatment, but a reasonable diet and avoidance of undue mental and physical exertion should be observed to secure the most satisfactory results from the histidine treatment.

The prompt improvement with the histidine treatment permits the patient to become ambulant early in the treatment and shortens the period of hospitalization to one month.

Patients with peptic ulcer tolerate a liberal diet, in the histidine treatment, even during the crisis.

The incidence of recurrence was reduced in cases of peptic ulcer receiving the histidine treatment, and all recurrent cases responded satisfactorily to a second treatment.

In tuberculous enterocolitis, the parenteral administration of histidine has been followed by rapid remission of diarrhoea and spastic abdominal pain. The general condition and the appetite improve.

Cases of peptic ulcer complicated by other diseases respond satisfactorily to the histidine treatment. The complicating disease should be treated at the same time.

The histidine treatment has been found of value in the treatment of gastro-intestinal ulcers other than peptic ulcer.

The parenteral administration of histidine in other diseases, particularly those of the respiratory tract, may be found of value.

The daily parenteral administration of histidine monohydrochloride has been found the therapy of choice in gastro-intestinal ulcers'.

Publishers' Notice

SCIENTIFIC Articles and Notes of interest to the profession in India are solicited. Contributors of Original Articles are entitled to receive 25 reprints *gratis*; additional reprints can be obtained on payment. No reprints will be supplied unless contributors ask for them at the time of submitting their manuscripts.

Communications on Editorial Matters, Articles, Letters and Books for Review should be addressed to THE EDITOR, *The Indian Medical Gazette*, c/o The Calcutta School of Tropical Medicine, Central Avenue, Calcutta.

Communications for the Publishers relating to Subscriptions and Advertisements should be addressed to THE PUBLISHERS, *The Indian Medical Gazette*, P. O. Box No. 54, Calcutta.

Annual Subscription to 'The Indian Medical Gazette', Rs. 16 including postage, in India. Rs. 19-8 including postage, abroad. Single copies Re. 1-8 each. Back numbers (if available) for the previous year Rs. 2-8 each, and all other back numbers Rs. 5 each.

Subscribers who so desire may have their copies packed flat in a strong envelope. The extra charge per annum is Re. 1-8 which should be added to the subscription. The envelopes are strongly made, and the *Gazette* is not folded, nor creased, in transit.

Papers and articles forwarded for publication are understood to be offered to *The Indian Medical Gazette* alone, and any breach of this rule will be followed by non-publication. When any such article appears in the *Indian Medical Gazette*, the copyright automatically becomes the joint property of the author or authors, and of the publishers.

The Editors of *The Indian Medical Gazette* cannot advise correspondents with regard to prescriptions, diagnosis, etc., nor can they recommend individual practitioners by name, as any such action would constitute a breach of professional etiquette.

THE TREATMENT OF PNEUMONIA BY MAY AND BAKER'S 693 : REPORT ON 50 CASES WITH CONTROLS

By AMIR CHAND, F.R.C.P.E.

LIEUTENANT-COLONEL, I.M.S.

Professor of Medicine, King Edward Medical College, Lahore

G. F. TAYLOR, M.A., M.R.C.P. (Lond.), MAJOR

Professor of Clinical Medicine, King Edward Medical College, Lahore

and

NAND LALL CHITKARA, M.B., B.S.

(Working with a grant from the Punjab Government)

M. & B. 693 was first prepared in the May and Baker's laboratory in England as a result of investigation made on the large number of new compounds following the work on prontosil and sulphanilamide during the last few years. It was made in the efforts to find a chemical compound which is active against the pneumococcus. Many previous allied compounds had been made which were active against pneumococci, but were too toxic for clinical use. This new compound, labelled M. and B. 693, was finally chosen because of its high activity and low toxicity, the most satisfactory 'therapeutic ratio'.

1. Chemical composition

The formula is stated to be

$$\text{NH}_2 \text{—} \text{C}_6\text{H}_4 \text{—} \text{SO}_2 \text{—} \text{NH} \text{—} \text{C}_5\text{H}_4\text{N}$$

and has the chemical name 2-sulphanilylaminopyridine. It is a white powder, melting at 190–193°C., with a slightly bitter taste and is soluble in water to the extent of 1 part in 1,000. The amount of the drug in the body fluids can easily be estimated by a method given in May and Baker's pamphlet on the use of the drug.

2. Absorption and excretion in animals and man

Experimental work on rabbits has shown that :—

- (a) the drug is rapidly absorbed from the intestines,
- (b) that the concentration of the drug in the blood reaches its maximum at the end of the second hour,
- (c) that it drops to half this maximum concentration in the blood at the fifth hour,
- (d) that it disappears entirely from the blood after 24 hours,
- (e) that the concentration in the cerebro-spinal fluid follows closely on that in the blood.

It was upon these observations that the four-hourly administration of the drug was originally based.

The work on human beings has given results similar to those on experimental animals. Baines and Wien found that M. & B. 693 appeared in the urine 45 minutes after one gramme had been given by mouth, that 60 per cent of it was eliminated in 24 hours and that it was completely eliminated in 50 hours. The concentration in the blood of human beings is at its maximum five hours after it is being given by the mouth.

Hobson reports the blood concentration in a male adult volunteer who received by mouth six doses of 1 gramme of M. & B. 693 at intervals of two hours. The maximum concentration of 10 mgm. per 100 c.cm. in the blood was reached between the third and fourth hour and was maintained for 24 hours, after which it quickly dropped to zero within the next 12 hours. This shows that doses repeated at short intervals will maintain a high concentration in the blood and also in the cerebro-spinal fluid.

3. Activity in experimental infections

The discovery of the activity of M. & B. 693 in experimental infections was made by Whitby (1938). Work had previously been done since 1935 on the action of various sulphonamide derivatives on pneumococci in Germany, France and England, which had shown that these compounds had some inhibitory action on pneumococci. Whitby worked on mice giving them M. & B. 693 by mouth by means of a stomach tube. He concluded that 'M. & B. 693 protects the mouse effectively against 10,000 lethal doses of pneumococcus type I and affords considerable protection against 10,000 lethal doses of other types of pneumococci'. He also showed that it was as effective as sulphanilamide against hæmolytic streptococcal and meningococcal infections.

Fleming (1938) working at St. Mary's Hospital, London, with delucocytised blood and defibrinated blood which had not been deprived of its leucocytes, showed that it is not bacteriocidal without leucocytes, but is strongly bacteriostatic, while with leucocytes it enhances enormously the anti-bacterial power of the blood, both to hæmolytic streptococci and pneumococci. He concluded that the increased anti-bacterial power lies in the serum. M. & B. 693 does not prevent encapsulation of the pneumococci. He describes methods for estimating the anti-bacterial power of the serum.

4. Clinical trials

The report of the first clinical trial of M. & B. 693 was made by Evans and Gaisford (1938) from Birmingham. They treated 100 cases of pneumonia with the drug and compared the results with 100 cases who were in the wards of their colleagues at the same time and were treated on ordinary lines without serum or

M. & B. 693. Of the 100 patients treated with M. & B. 693, 8 only died, while in the 100 control cases there was a mortality of 27 per cent. The 27 per cent mortality corresponded to the usual mortality of cases in Birmingham at that time of the year. They noted that the drug caused a dramatic fall in temperature in the first 24 hours in 37 per cent of the cases, and in a further 23 per cent in the next 24 hours. No case of granulopænia was noted. Of the complications, they noted a higher number of empyemas in the treated cases, there being 6 in the treated and only 1 in the controls. The usual number of empyemas in pneumonia is given by Osler as 2 to 3 per cent. No conclusion was reached as to influence on various types, but work is being done on this in Birmingham and has not been reported as yet.

The drug has been given an extensive trial in the mines of Johannesburg, where it is reported that no native had died of pneumonia in the mines for the last three months. Exact details of this report have not as yet been obtained by us.

5. Use in pneumococcal meningitis and gonorrhœa

There are reports of recovery of two cases of pneumococcal meningitis treated with M. & B. 693 (Reid and Dyke, 1938, and Robertson, 1938). Price (1937) stated that 'No cases of recovery from this form of meningitis has hitherto been recorded'.

It has been used also in gonorrhœa. Prebble (1938) reported the trial of M. & B. 693 in 65 cases of acute gonorrhœa and concluded that it is the most active of the chemotherapeutic substances combined with a low toxicity, in this disease.

controls; both lobar and broncho-pneumonia were included. With a few exceptions cases have been treated alternately with M. & B. 693 and by ordinary means, but in 2 or 3 cases strict alternation of cases has not been followed, M. & B. 693 being given to the more serious cases.

The dose was according to the plan worked out by Gaisford and Evans in Birmingham and recommended by May and Baker, namely, 4 tablets each of 0.5 gram on admission, repeated 4 hours later, a further 2 tablets 4 hourly for 36 hours, followed by 1 tablet 4 hourly for a further 36 hours. The plan of doses was interfered with, in some cases, by vomiting. In some cases the drug was not given if the patient was asleep.

Of the 50 cases treated with the drug, 5 cases died giving a mortality of 10 per cent. Of the control cases there were 9 deaths, i.e., a mortality of 18 per cent.

Eleven cases of pneumonia came to the hospital during this period in a moribund condition and died within the first 24 hours in hospital and have not been included, either in the control or treated lists of cases.

In the 50 treated cases, 2 deaths occurred in 24 cases who came to the hospital during the first five days of the pneumonia, i.e., a mortality of 8.5 per cent, and 3 deaths occurred in 26 cases who came on the fifth day or after, i.e., a mortality of 11.5 per cent.

In the control group 16 cases came to the hospital during the first five days of whom 1 died, a mortality of 6.25 per cent, while 34 cases came on the fifth day or after of whom 8 died, a mortality of 23.75 per cent.

These figures are set out in the following table :—

	Total	Total deaths	Total treated before five days	Death	Total treated on fifth day or after	Death
M. & B. 693	50	5 or 10 per cent *	24	2 or 8.5 per cent.	26	3 or 11.5 per cent.
CONTROLS ..	50	9 or 18 per cent *	16	1 or 6.25 per cent.	34	8 or 23.75 per cent.

* This difference is far from 'significant' statistically, and, in an infinite number of experiments, in which two groups of patients were treated by exactly the same method, this—or a greater difference—would be observed once in every three times.

On the other hand, the differences which these writers show in the time of fall of temperature in the two groups is 'very significant', statistically.—EDITOR, *I. M. G.*

6. Report of the trial in the Mayo Hospital, Lahore

During the last two months, December 1938 and January 1939, 50 cases of pneumococcal pneumonia have been treated in the Mayo Hospital, Lahore, with M. & B. 693 and 50 kept as

The most striking result of M. & B. 693 treatment is that the temperature comes down to normal within 24 or 48 hours of giving the drug. This was noted by Gaisford and Evans and was obvious in this Lahore group. In 39 cases of the treated group, the temperature fell to normal

in 48 hours, i.e., in 78 per cent of the treated cases. In the control group however only 1 case of the 50 had a normal temperature within 48 hours of admission to hospital. In 28 of the 50 treated cases the temperature was normal on or before the sixth day while in only 3 out of the 50 'controls' was the temperature normal as the result of normal crisis on or before the sixth day of disease.

This is shown also by the following table :—

	Total cases	Average days of temperature in hospital	Average stay in hospital
M. & B. 693	50	2.7	9.9
CONTROLS ..	50	5.96	13.8

8. Complications

Vomiting.—This occurred in 16 cases of the treated group and is apparently due to the action of the drug on the stomach. A supply of the drug suitable for injection has been obtained and will be used in future for those who vomit. As yet no experience of these injections is available.

Leucopenia.—This was noted in one case. White blood cell counts were done in all cases at intervals. In one case treated with M. & B. 693 the white cells fell from 25,000 to 12,000 during treatment, but there were no adverse clinical signs. The patient made an uninterrupted recovery.

Vomiting was the only complication of any importance noted though the following complications are recorded by other workers: headache, nausea, breathlessness, dizziness, lassitude, general malaise, drug rash and fever, cyanosis and methæmoglobinæmia.

Unresolved pneumonia.—This was noted in 3 cases treated with 693 and in 3 of the controls.

Empyema.—This has occurred in 2 treated cases one of whom is not included in this group as he is still in the hospital, while none occurred in the controls. This agrees with the findings of the Birmingham workers that empyema is commoner in cases treated with M. & B. 693. In these two cases the empyema has been aspirated by a syringe and needle and the cases treated with M. & B. 693 without operation. They are progressing satisfactorily and it appears that operation will not be necessary. One has been discharged as cured.

Further experience is needed before coming to any conclusions as to the value of the drug in pneumococcal empyema.

An enlarged spleen due to previous malarial infection was noted in 6 of the M. & B. 693 cases and in 3 'controls' and received appropriate treatment.

In many of the M. & B. 693 treated cases the sputum remained blood stained when the temperature came to normal. Clinically, there was

no obvious sign that resolution took place in an abnormal way or at an earlier or later period than in the untreated cases.

Retention of urine was noted in 2 cases.

Subnormal temperature was noted in 2 cases after treatment was completed.

Owing to delay in obtaining type sera from America, the typing of pneumococci has only been done during the last few weeks. It is proposed to type all future cases and to obtain information as to the relation of the type of pneumococcus to the therapeutics of the drug.

The Punjab Government has given a grant for anti-pneumococcal Felton's serum. This will be tried in pneumonia with and without M. & B. 693 in the Mayo Hospital during the next year in order to assess the value of serum treatment.

During this period 4 cases of pneumococcal meningitis following pneumonia were admitted and treated with full doses of M. & B. 693—all died. Recently a case of primary pneumococcal meningitis has been treated with M. & B. 693 outside the hospital and he has recovered completely without any complication.

Summary and Conclusions

From the above the following conclusions are drawn :—

The mortality is greatly reduced by the use of the drug in this series of cases—from 18 per cent in untreated cases to 10 per cent in the treated.

By the use of M. & B. 693 the days of raised temperature in hospital are greatly reduced, from an average of 5.96 days in the controls to 2.7 days in the treated.

The stay in hospital is reduced on the average by four days. Most cases were kept in the hospital until signs of resolution were complete. Some cases in both groups left against medical advice.

It is obvious that for statistical purposes these figures are too small in number to draw final conclusions, but, taken with other published results, they indicate the value of this new drug.

Vomiting was the only complication of any importance noted and it occurred in 32 of the M. & B. 693 treated cases. There appears to be no serious toxic action of the drug.

Both from the clinical day-to-day study of these cases and from a study of the cases reported elsewhere, we think there is convincing evidence that M. & B. 693 should be given to all cases of pneumococcal pneumonia as the routine treatment until a better drug be made available. Further evidence as to its value will accumulate rapidly. Knowledge of the use of concentrated anti-pneumococcal serum used with M. & B. 693 will be available within the next year or two. But it is unlikely that serum will come into general use in pneumonia because of its expense.

CLINICAL OBSERVATIONS ON PNEUMONIA OCCURRING IN A TEA-GARDEN IN ASSAM

By SAILESH CHANDRA DUTTA, L.M.P.

Assistant Medical Officer, Itakhooli Tea Estate,
Tinsukia, Assam

THE literature dealing with pneumonia is already voluminous, but surprisingly uninformed regarding the clinical types found in Assam. I therefore feel that no apology for the present observations is needed. Bhattacharyya (1936) reviewing 233 cases of pneumonia occurring in an estate near Doom Dooma found that 'atypical clinical pictures were more common than the classical pictures of textbooks'. The present communication deals with 102 consecutive cases observed from January 1937 to June 1938 and is an attempt to assess the importance of certain factors in ætiology and prognosis, to describe the clinical picture, and to assess the value of different modes of treatment.

Population.—The population of the garden is about 2,400. The majority being new recruits, are unacclimatized. Addiction to alcohol is a common habit.

Climate.—The climate is hot and moist in summer, cold and dry in winter. The maximum temperature in summer is a little below 100°F. and the minimum temperature in winter goes down to about 48°F. During the months from March to October the minimum temperature is above 60°F. The maximum range of diurnal variation is during the change of seasons, but in summer also weather is very changeable. Rain-fall is heavy during June, July and August. Heavy showers of rain alternating with hot sunshine are the characteristic features of weather during these months.

Age and sex.—Incidence by age and sex has been summarized in table I. Both sexes were almost equally affected in children, and males slightly predominated after ten years onwards. In labouring-class people, females are equally

TABLE I

Sex	AGE GROUP IN YEARS								Total
	Under 1	1-5	6-10	11-20	21-30	31-40	41-50	51-60	
Male ..	6	12	4	4	7	15	4	3	55
Female ..	4	16	4	6	10	6	1	Nil	47
TOTAL ..	10	28	8	10	17	21	5	3	102

INCIDENCE

The following factors affecting incidence will be considered—population, climate, age, sex and time of year.

(Continued from previous page)

This group of cases is small but they are collected to confirm for Indian patients the work done in England and elsewhere and to bring to the notice of medical practitioners the value of this new drug.

Acknowledgment.—I wish to thank Rai Bahadur Jiwan Lal for his collaboration, Dr. Mohd. Yusuf for his very helpful criticism, May and Baker for supplying some of the M. & B. 693 used and Mrs. Bharucha for supplying funds to buy the remainder.

clothing (which is unavoidable) is of more importance than atmospheric temperature.

CLINICAL PICTURE

In this series there were 57 cases of lobar and 45 cases of broncho-pneumonia. Among the lobar cases were seven secondary to influenza. There were four central cases, one abortiform case and one case in a lunatic. Both the lungs were affected in only two cases. No apical type was found.

It is my confirmed opinion that most of the cases found in this part of India are atypical and do not follow the textbook type. This observation corresponds with that of Bhattacharyya (*loc. cit.*). It is particularly difficult to diagnose a case at the beginning and still more difficult to differentiate lobar cases from broncho-pneumonia and influenzal types.

Lobar pneumonia.—Onset of the disease is gradual with low temperature, generalized pain in the body and a little or no cough. Then gradually the temperature rises, pain becomes localized, dyspnoea begins and there is harassing cough with or without a little mucoid expectoration. Sudden onset with high temperature, dyspnoea, rigor and acute pain in chest is rare. The pyrexia may be continuous or irregularly remittent. It lasts as a rule for two or three days and finally remits by crisis. The patient feels almost well. There are no dyspnoea, no pain in chest, cough is productive and pulse rate is within normal limits. In other cases the pyrexia does not remit or, after the characteristic remission, the temperature may rise sharply again and remain continuously high. The dyspnoea is marked with varying degree of toxæmia and the patient is in acute distress. Delirium is a common accompaniment. The sputum is rusty now. The temperature ultimately comes down by lysis in the majority of these cases. Pulse and respiration rate gradually return to normal limits, cough is purulent and productive. I have found that pulse-respiration ratio in lobar cases varies between 3 to 1 and 2 to 1. Bradycardia is found during convalescence in many cases in which the temperature comes down by crisis. Pulmonary signs of the disease may be completely absent for the first two or three days; but generally fine crepitations or friction sounds are found. In cases where temperature comes down within two or three days, no dull area is discoverable at all. After crisis moist sounds persist only for two or three days.

In cases where pyrexia persists for a longer period, a dull area is found rather late, on the fourth or fifth day. The extent of the lesion does not seem to have any relation to lobar limitations. In some cases only a small portion of one lobe is affected and the lesion does not increase. In others the consolidation extends from one lobe to another. No selective affinity for the right base is found. Breath sounds are generally harsh, but are inaudible when pleural

involvement is marked. Typical tubular breathing is rarely found. After cessation of pyrexia, redux crepitations and bubbling râles persist for a long period.

Broncho-pneumonia.—These cases are still more atypical in their mode of onset and subsequent course. Admission with moderate pyrexia, loose sputum, running from eyes and nose, a haggard look, and irritable temper is the rule. Many are admitted with gastrointestinal symptoms, *e.g.*, vomiting and diarrhoea. Convulsions and signs of cerebral irritation are rare. Dyspnoea is marked and pulse rate is very high. Generally the pulse respiration ratio is 2 to 1 or less. The temperature chart is very variable. The pyrexia may be intermittent, remittent or continuous or an irregular combination of all. Sudden change of temperature to intermittent character is also common. In long-standing cases, the temperature settles down by lysis and in favourable early cases by crisis.

The physical signs are also variable. Almost all the cases are admitted with bubbling râles scattered in both lungs. In the majority of cases, however, after a day or two, crepitations and rhonchi are found in limited patchy areas. Consolidation is rarely found although pyrexia may persist for a long period with severe toxæmia and cyanosis. Breath sounds are loud and harsh and constantly changeable. Cough is non-productive except when the child vomits. Adventitious sounds in lungs persist for a long time after cessation of pyrexia. Considering the mode of onset, course of temperature and pulmonary signs, I would like to call these cases 'influenzal'. Typical primary broncho-pneumonia is rare.

PROGNOSIS

The outcome of the disease may be affected by the attitude of the patient, the existence of concurrent disease and the severity of the pneumonic process. Among tea-garden labourers especially, prognosis can be so gravely influenced by the patient's attitude that I propose to enumerate the dangers rather more fully.

Posture.—Complete rest in a patient is difficult to secure. He will suddenly get up from bed, for no apparent reason or to pass excreta. He seldom uses the bed-pan or takes nourishment in a lying posture. This behaviour seriously affects prognosis. Sudden collapse without any warning sign is mainly attributable to this cause.

Refusal of treatment.—The patient will sometimes resist some of the general measures to be undertaken, *e.g.*, warm bandage on chest, cold douching on head, sponging of the body and the giving of enemata. To manage such a case is a matter of tactfulness and the maintenance of a convincing attitude by the attending physician.

Diet.—Rice is the main item of the dietary of these people and they think that in disease

too this is the only thing that maintains strength. It is a common occurrence at night for some of the patient's relatives to come in with a small dish of rice and fowl curry; the patient takes it and is attacked with obstinate tympanites next morning.

Late admission to hospital.—This is unfortunately a characteristic of labouring-class communities throughout the world.

Excessive alcoholism.—Virtually all coolies who are old enough to take alcoholic liquor do so to excess.

Concurrent disease.—Pneumonia in a malarial or anæmic subject is common here. In my experience, anæmia makes for a bad prognosis, malaria does not.

Severity of the pneumonic process.—Signs of bad augury are as follows:—

(a) Severe dyspnoea and cyanosis, (b) anorexia, (c) obstinate insomnia, (d) obstinate tympanites, (e) muttering delirium, and (f) irregular pulse.

Complications and sequelæ

In this series serious complications were rare. The following were the complications found:—

(a) Violent delirium	1 case
(b) Venous thrombosis of both legs	1 "
(c) Œdema of lower extremities ..	9 cases
(d) Otitis	3 "

Most of the cases, being repatriated to their country, could not be followed. One patient of this series expired from an attack of bacillary dysentery afterwards.

Treatment

The treatment of pneumonia remains a difficult problem still. Immediately any departure is made from the sheet anchor of complete rest and good nursing, we enter into the realms of controversy. Many drugs have betrayed the too-trusting physicians and even regarding the use of digitalis, alcohol, oxygen, and local applications, there is no unanimity of opinion. Specific serum has been successful against types I and II but appears to be of little value against other types. Moreover, Napier and Dharmendra (1935) claim that types I and II are very rare in Assam and that only sera prepared against the types normally found in Assam are likely to be of much value.

A number of non-specific protein compounds and antigenic preparations have been introduced for the treatment of the acute infections and have received favourable mention by clinical workers after more or less extensive trial in cases of pneumonia. Potassium iodide is a remedy of ancient lineage and intravenous injections of iodine have been, and are, popular with other workers.

The scheme of treatment, I personally use in my hospital for cases of pneumonia, is as follows:—

(1) Complete rest in bed, and taking nourishment and passing excreta in the lying posture, is insisted on.

(2) The patient is covered with light blankets and kept near an open window.

(3) The chest is wrapped with a layer of cotton wool and loosely bandaged.

(4) Cold douching to the head at noon daily.

(5) Liniment camphor ammoniata mixed with equal parts of mustard oil applied locally.

(6) Plenty of glucose drink (20 per cent with sodium bicarbonate a drachm to a pint) is supplied.

(7) Sago, barley water, milk and weak tea form the main dietary.

(8) *Expectorants*.—In adults for the first two days alkaline mixture containing potassium citrate, sodium bicarbonate and tincture scillæ is given and is replaced, on the third day, by a mixture containing potassium iodide, creosote, aromatic spirits of ammonia and tincture senega. When the sputum is loose, ordinary stimulant mixture containing aromatic spirits of ammonia, spiritus ætheris sulphuricum and compound tincture of cardamom is substituted.

In children.—For the first two days, the alkaline mixture as in adults with compound tincture of camphor, if necessary, is used. From the third day, a mixture containing Thiocol, aromatic spirits of ammonia, tincture ipecacuanhæ and extract glycyrrhiza liquid is found most useful.

(9) In addition to the general treatment outlined above, every case is treated with one of the following: Intravenous iodine, S. U. P. 36 and Omnadin.

(10) *Emergency measures*.—

(a) Cardiac failure—in my experience digitalis from the beginning has no special advantage. In emergency, Tincture digitalis mxx—thrice daily and subcutaneous injection of strychnine and digitalin combined have been found useful.

(b) Tympanites—turpentine stupe to the abdomen and pituitrin injection.

(c) Sleeplessness—paraldehyde two drachms at night. If insomnia is mainly due to cardiac embarrassment, an injection of digitalin and strychnine is given in addition to the paraldehyde.

(d) Violent delirium—hyoscine hydrobromide has been found quite useful.

(e) Spasmodic cough—steam inhalation from bronchitis kettle with compound tincture of benzoin a drachm to a pint, in the water, ensures rest and relief to the children with spasmodic cough or with dry cough in the early stage of the disease.

When intravenous iodine is used in treatment, the technique adopted in this hospital

is as follows : For one injection, $\frac{1}{2}$ gr. of pure iodine is dissolved in 10 c.cm. of sterile distilled water containing 1 gr. of potassium iodide. The injection is given slowly into a vein and caution exercised so that no solution escapes in the subcutaneous tissue. An indurated swelling of the part may appear from the irritating solution going outside the vein. But this never suppurates and is successfully treated with 50 per cent methylated spirit compress and glucose drink.

There seems to be no contra-indication except tuberculosis. No bad effect was found immediately after injection except in one patient who complained of faintness and had a rigor after injection. It was a hot summer day and he soon recovered with general measures. No remote bad effect or signs of intolerance were found even after one daily injection on four consecutive days. Intravenous iodine therapy has obvious disadvantages in the treatment of children.

Of the 102 cases in this series, one was of abortiform type, the fever remitting on the second day; one was a terminal case and two cases were admitted very late in a precarious condition and expired within twenty-four hours. These cases were treated on general lines only and will not be considered further.

Thirty cases were treated with intravenous iodine, 29 cases with S. U. P. 36, 23 cases with omnadin, and 16 cases with different combinations of the above three.

Combined treatment was generally given in resistant cases when one or other alone failed to control the disease in a reasonable period. This group is, therefore, not strictly comparable with the other three.

No control cases were kept, as previous experience on this estate had given me the impression that these additional forms of treatment resulted in more rapid discharge of patients and the exigencies of service prevented the adoption of a purely experimental attitude.

The results of treatment are summarized in the following tables.

Table III shows the average number of injections required for each case. No more than four consecutive injections of iodine or omnadin and no more than three injections of S. U. P. 36 were given in any one case.

TABLE III

Treatment	Number of cases	Average number of injections in each case
Iodine ..	30	2.6
S. U. P. 36 ..	29	2.0
Omnadin ..	23	2.4
Combined ..	16	4.7
TOTAL ..	98	2.7

Table IV shows that the average days of pyrexia in each case was seven. The maximum period of pyrexia in lobar cases was 19 days; and in broncho-pneumonia cases 29 days.

TABLE IV

Treatment	Number of cases	Average days of pyrexia in each case
Iodine ..	30	5.4
S. U. P. 36 ..	29	5.4
Omnadin ..	23	6.2
Combined ..	16	13.2
TOTAL ..	98	6.9

Temperature came down by crisis in 44 cases out of 88; one abortiform case and 13 fatal cases being excluded. Table V shows that the highest percentage of crisis cases was in the iodine-treated series.

TABLE V

Treatment	Number of cases	Crisis case	Percentage
Iodine ..	29	19	65.5
S. U. P. 36 ..	25	12	48.0
Omnadin ..	22	11	50.0
Combined ..	12	2	16.6
TOTAL ..	88	44	50.0

Table VI demonstrates the mortality in each mode of treatment. Here the cases are divided into three groups according to the day of admission. Admission on the first day of disease was considered to be early, on the second and third days to be moderately early and from the fourth day onwards, to be late.

The mortality in iodine-treated cases was 3.3 per cent. There was no fatality in early or moderately early cases, and in late cases too it proved useful.

Omnadin was almost equally effective in early and moderately early cases but less effective than iodine in late cases.

S. U. P. 36 proved useful in early cases, less so in moderately early cases and practically of no use in late cases.

In the 'combined treatment' group the mortality was 25 per cent. As shown in table IV these were the most resistant cases.

The gross mortality in my series was 12.7 per cent. Here, I must mention that every pneumonia case occurring in the garden during this period of observation was brought into the hospital.

The paramount importance of early admission to the hospital is also clear from table VI.

TABLE VI

Treatment	EARLY			MODERATELY EARLY			LATE			TOTAL		
	Cases	Death	Per-centage	Cases	Death	Per-centage	Cases	Death	Per-centage	Cases	Death	Per-centage
Iodine	12	Nil	..	11	Nil	..	7	1	14.3	30	1	3.3
S. U. P. 36	13	Nil	..	11	1	9.1	5	3	60.0	29	4	13.8
Omnadin	8	Nil	..	11	Nil	..	4	1	25.0	23	1	4.3
Combined	3	Nil	..	6	4	66.6	7	Nil	..	16	4	25.0
No special	2	1	50.0	Nil	2	2	100.0	4	3	75.0
TOTAL	38	1	2.6	39	5	12.8	25	7	28.0	102	13	12.7

In early cases the mortality rate was only 2.6 per cent and the prognosis worsened according as the cases were admitted later in the disease.

Table VII shows the mortality by age. There was no death in the age group six to ten years. This is an interesting but generally recognized finding. It is evident that the prognosis is worse after forty years of age.

TABLE VII

Age groups in years	Number of cases	Death	Percentage
Under 1	10	1	10.0
1 to 5	28	4	14.3
6 to 10	8	Nil	..
11 to 20	10	1	10.0
21 to 30	17	2	11.8
31 to 40	21	3	14.3
41 to 50	5	1	20.0
51 to 60	3	1	33.3
TOTAL	102	13	12.7

Table VIII shows that the mortality rate differs a little in the two types*.

TABLE VIII

Type	Number of cases	Death	Percentage
Lobar	57	8	14.0
Broncho.	45	5	11.1
TOTAL	102	13	12.7

Conclusion

It is evident that the pneumonia cases found on this estate do not follow the classical types

* This difference is far below the 'significance' level statistically.—EDITOR, I. M. G.

in their incidence and clinical picture. It is logical to think that their bacteriology and pneumococcal typing will also differ.

Compared with S. U. P. 36 and omnadin, intravenous iodine has proved most useful in the treatment of pneumonia. It is a very cheap treatment and deserves extensive clinical trial.

Summary

(1) The clinical aspects of 102 consecutive cases of pneumonia occurring on a tea garden in Assam are discussed.

(2) The sexes are found to be equally susceptible and no age is exempt. The heaviest incidence occurs in the first and fourth decades of life and during the wet summer months.

(3) The clinical picture, as a rule, is atypical.

(4) Omnadin, S. U. P. 36 and intravenous iodine have been extensively tried and their results compared. The technique of intravenous iodine is discussed.

(5) Prognosis is not affected by the type of pneumonia. It is worst in patients over forty years of age and in cases admitted to hospital late in the disease.

Acknowledgment

My thanks are due to my chief Dr. K. P. Hare, to whom I owe a deep debt of gratitude for encouragement and valuable help in the preparation of this paper.

My thanks are also due to Mr. F. O'Connor, the manager of the garden, for his kind permission to publish this paper.

My thanks are also due to Sjt. K. C. Handique and my hospital assistant, Babu A. C. Das, for necessary help.

LECITHIN AND GLUCOSE IN THE TREATMENT OF THE OPIUM HABIT

By S. C. GUHA ROY, L.M.S.

Assistant Medical Officer, Borbhecl Tea Company, Limited, Borgang P. O., Assam

Our attention having been drawn to the treatment of the opium habit by lecithin and glucose by a paper in this journal by Chopra and Chopra (1937), we decided to treat the opium addicts living on this garden. There were 96 opium addicts amongst the garden labourers, who had emigrated mainly from the Cuttack district and had been settled here for many years. The opium habit has lowered them both morally and physically, and turned them into a group of lower-grade labourers. The manager, Mr. F. T. H. Hearn, has taken great interest in the treatment, and with his help and encouragement we have treated 38 cases with the most encouraging results. The remaining addicts, except those who are physically unfit, will be also taken in hand.

The following tables will show the cases treated :—

Sex and age of addicts

Ages	Male	Female	Total
15-20 years ..	1	1	2
21-30 " ..	8	4	12
31-40 " ..	8	5	13

Eating	14
Combined smoking and eating	7

Treatment.—Addicts were taken as indoor sick in batches of six, and received the same daily wage that they would have earned on the garden. After a preliminary examination the selected cases handed over their opium licences, which were sent back to Government, and their ration was abruptly stopped. Usually they were admitted in the morning, after taking their morning dose of the drug and the treatment commenced with ovo-lecithin in pills of gr. 10 thrice a day and glucose water (1 in 6) *ad lib.* for the first five or six days. The first night calomel was given and was followed by a free dose of magnesium sulphate next morning. We could not examine the urine to detect morphia, but we were satisfied that the report of our watchman and of the other patients, that opium was not being taken, was correct. The first batch was selected from volunteers and the success with this batch encouraged the other addicts to think that the opium habit could be given up. Realizing the amount of money they would save through abandoning the habit, as contraband opium is said to be sold at Rs. 6 per tola, there was considerable competition to be chosen for the next batch. Even very old and physically unfit people requested to be treated. We noticed that the will-power of the addicts played a good part in the treatment.

Symptoms varied considerably according to the accustomed dose, duration of habit and general health. During the first 24 hours, patients complained of general discomfort which turned worse at the times at which they had been accustomed to take the drug. Muscular pain all over the body, specially in the limbs, and often severe cramp in calf muscles were typical symptoms.

Insomnia added to their general discomfort. This condition continued for three to five days and then gradually lessened until the tenth to fifteenth day, after which the symptoms disappeared. They were treated with massage, aspirin, bromide, hyoscine hydrobromide, paraldehyde and medinal.

Other symptoms noted were epigastric pain, hiccough and running from nose and eyes. Some complained of mild nausea, vomiting, diarrhoea or constipation. For these the usual treatment was given.

For the first few days their appetite remained very poor and they were given *dohi*, *chirra* and *soojee*, but it improved gradually on a soda and gentian mixture and they were put on the usual hospital full diet. General weakness needed care afterwards with tonic. The majority of patients shook off the symptoms after two weeks, but were detained another week in hospital to recoup their general health. They told us after the first week that they lost all desire for opium. Most of them were markedly improved in general health at the time of discharge.

A SIMPLE AND INEXPENSIVE METHOD OF INTRA-TRACHEAL ANÆSTHESIA

By M. C. GANGULI, M.B. (Cal.), D.A. (Eng.)
Anæsthetist, Medical College Hospitals, Calcutta

PROBABLY a few lines as a plea for the more extensive use of intra-tracheal anæsthesia in this country, especially for operations on the mouth, face, head and neck, will not be deemed out of place.

Though operations on these parts can be performed by some form of rectal anæsthesia—avertin or ether-oil, or intra-pharyngeal methods, in each case the anæsthetist has to maintain an efficient airway by manipulations of the jaw, not without some inconvenience to the surgeon and risk of infection of the wound from his hands, even though gloved. Moreover, during operations within the mouth the surgeon and his

(Continued from previous page)

Short notes on three cases are given below :—

Case 1.—A male, aged 48 years, taking raw opium, 18 grs. daily in three doses for about 18 years.

Cramps in calf muscles remained very bad for about three weeks.

Case 2.—A male, aged 50 years, smoking 18 grs. of opium daily in three doses for about 25 years.

On the third night of treatment he was on the verge of collapse with profuse perspiration and feeble pulse but reacted soon to stimulants. Insomnia and general debility were very troublesome with him. He is a garden sirdar, and is now working well and of better physique than before.

Case 3.—A male, aged 60 years, taking raw opium, 12 grs. daily in two doses for about 30 years. He is old with all signs of senile decay. Against our advice he volunteered to undergo the treatment and patiently endured a great deal of discomfort. He has now given up opium for one and a half months, but suffers from general debility and occasional pain in the abdomen.

Four addicts gave up the habit without hospital treatment. They cut the dose gradually and took to drink instead—the lesser of two evils! More are following in their footsteps. The treated cases are under observation and as far as we know they have not gone back to opium and most of them are markedly improved in health.

I must finish by thanking the chief medical officers, J. R. Robertson and H. H. Davies, for their kind advice and encouragement.

Summary

1. Thirty-eight cases of opium addicts were treated in a tea-garden hospital with cent per cent success.

2. With the co-operation of the addict the treatment was easier than had been expected.

assistants have to be always on the alert to prevent any aspiration of blood within the air passages. The intra-tracheal catheter, maintaining as it does an automatic and efficient airway in any position of the head and neck and an intra-pharyngeal plug preventing any chance of entry of blood into the trachea, a sense of security is given both to the surgeon and the anæsthetist, which neither will like to forego.

But a great drawback of intra-tracheal anæsthesia lies in the rather expensive and complicated machines which are necessary and which unfortunately few of our hospitals in India can afford to possess. For some time the writer has been using a very simple method requiring but a few appliances, the cost of which is within the financial capacity of most hospitals*.

The technique has so far worked quite satisfactorily and the details are given below (figure 1).

The patient having been anæsthetized with chloroform-ether sequence an intra-tracheal catheter (c) of adequate bore is introduced into the trachea under a direct-vision laryngoscope in the usual way and the pharynx plugged with moist rolled gauze. A dental prop or gag placed in position prevents the catheter from being bitten. The projecting part of the catheter is now strapped to the forehead with adhesive plaster and its end fixed to a rubber tube about three inches long which is connected to one limb of a metal Y tube (e). Another limb of this Y tube is connected to a biggish glass funnel covered with a double layer of lint by rubber tubing about a foot and a half long. If the opening in the third limb of the Y tube is now closed, either with a finger or with a cotton-wool plug (d), the lint on the funnel will be seen to move up *a* and down *b* with each act of expiration and inspiration. The funnel is placed on its side on a table and ether dropped on the surface of the lint. A few drops of chloroform are sometimes of advantage during the early stages. The funnel should not be held erect as liquid ether may be aspirated into the trachea with disastrous consequences in case an undue excess is poured on the lint. This danger can however be avoided by using a glass or copper can with an open top and a spout fixed near to

*The approximate cost of the appliances required is about Rs. 90 as below.

	Rs.
A laryngoscope with flexible wire and dry cell	65
(Magill's type has the battery fixed within the handle.)	
$\frac{1}{2}$ dozen intra-tracheal catheters ..	20
Funnel, rubber tubing, and Y tube ..	5
TOTAL ..	90 only

The cost can however be reduced to a minimum of about Rs. 20 only if pernasal blind intubation is resorted to with Magill's tube, but failure in about 30 per cent of cases is to be expected.

the top in place of the funnel (figure 2). The open top can be covered with lint and any excess on it will settle at the bottom of the can without

Thanks are due to Mr. D. C. Chakravarty, M.B.D., F.R.C.S., Professor of Clinical and Operative Surgery, Medical College, Calcutta, for his

Fig. 2.

any chance of being aspirated into the air passages. The ether vapour can also be warmed to the appropriate temperature by placing the can in a water-bath. Copper is to be preferred for the can because it can be easily made to order, and is cheap in the long run, not being fragile like glass. Moreover copper is an anti-catalyst to ether.

The cotton-wool plug on the third limb of the Y tube is occasionally removed to allow entry of more air. The open end of this limb can also be connected to the delivery tube of an oxygen or carbon-dioxide cylinder if required. The lint may be covered with a towel if a more concentrated ether vapour is necessary at times.

It may appear that having had to breathe through two layers of lint the meshes of which are partially filled with ether undue respiratory efforts are required on the part of the patient and if the process goes on for any length of time the patient may be exhausted. In fact, no such ill effect need be feared as the resistance offered by the lint to the gases during respiration has been found to be below 5 mm. Hg. and no signs of exhaustion were ever noticed after anaesthesia of an hour's duration.

The operations that have been performed under this funnel-lint intra-tracheal anaesthesia are for cleft palate, parotid fistula, mixed parotid tumour, mixed tumour of the sub-maxillary gland, radium implantation in carcinoma of the tongue and cheek, ranula, parenchymatous goitre and adenoma thyroid.

The ages of these patients varied from nine to sixty years, the maximum weight was fourteen stone and the longest duration of operation was fifty minutes. No untoward effects have been observed in any of the cases during the operation or after.

kind encouragement and permission to try this method on his cases.

SOME EXPERIMENTS ON THE ABSORPTION OF INSULIN WITH SPECIAL REFERENCE TO ABSORPTION THROUGH THE NASAL PASSAGES

By F. W. ALLINSON

CAPTAIN, I.M.S.

First Resident Medical Officer, Presidency General Hospital, Calcutta

and
S. PAUL

Biochemist, Presidency General Hospital, Calcutta

THERE is no question that the injection of insulin subcutaneously is at the moment the best method of administration, if exact dosage is necessary and wastage is to be avoided. The giving of insulin however by this method causes a considerable inconvenience to patients, especially children and those who are too poor to afford skilled medical attendance or too ignorant to give their own injections.

Attempts have been made to produce an insulin which will be efficacious if given by mouth, and other glandular and vegetable products and drugs have also been tried but with little or no success. Insulin given by this route has so far failed as the pH of the digestive juices of the mouth and intestinal tract have been unsuitable. The other routes chosen for absorption, such as the ear and conjunctival sac, have been impracticable.

These various paths of absorption have been tried by a considerable number of workers, but we can find no trace in the literature of absorption of insulin through the nasal passages*.

*[Attention is drawn to the following paper:—Major, R. H. (1935). The Intranasal Application of Insulin. *Journ. Lab. and Clin. Med.*, Vol. XXI, p. 278.—EDITOR, I. M. G.]

We first tried this method using the most concentrated solution of insulin on the market, namely, 100 units per c.cm. of solution. As it was obvious that the absorption would not be as great as by injection a much higher dosage was given. Thus in one case a boy who was getting 60 units of zinc protamine insulin daily was given 110 units by the nasal route. It was found that by this method quite an appreciable lowering of the blood sugar occurred, but the difficulty of instilling as much as 1 c.cm. of solution into the nose was a great disadvantage.

We next decided to use a much more concentrated solution of insulin, and for this purpose obtained crystalline insulin from Messrs. Burroughs Wellcome & Co. We used a solution containing roughly 50 units per drop and in most cases two drops were instilled into the nostrils of our diabetic patients. The symptomatic effect on the patients was apparent within half an hour or so, any heaviness in the head or headache disappeared and there was a sense of general well-being. One patient was also relieved of a tingling sensation in the head and hands. The blood sugar examinations showed a marked reduction in the first 2 hours after instillation of the insulin into the nose, and the urine, which was loaded with sugar before, showed a marked change in sugar content when tested with Benedict's solution.

The results of our experiments are given below and it will be seen that insulin is absorbed by the nasal mucous membrane to a greater extent than from the other mucous surfaces yet tried. The great advantages of this route of absorption are obvious, but the disadvantages are the expense, as large quantities of insulin are required, and the difficulty in estimating the exact dosage; this will probably vary with different

THE TREATMENT OF ACUTE AND CHRONIC DIARRHŒA WITH A SALT-FREE DIET*

By PROFESSOR DR. HUGO SALOMON
Buenos Aires

THE principles for the treatment of diarrhœa have changed in the last few decades. Little by little the dogma of the treatment of acute diarrhœa by giving a laxative to remove as soon as possible the 'materia peccans' toxic substances, secondarily formed, is being questioned. The therapeutical act of giving a laxative very often causes a diarrhœa that is difficult to interrupt. One does not know how the illness would have developed without a laxative, but during the course of a very long experience I have come to the conclusion that the course of the illness is more favourable, if one has confidence that the body will clear itself sufficiently by the severe diarrhœa, without it being necessary to increase this diarrhœa. I have defended this opinion already in an article on the treatment of dysentery (Salomon 1915).

*Rearranged by the Editor.

(Continued from previous column)

individuals and with varying conditions of the nasal mucous membrane at any given time.

It is early to assess the value of these experiments, but we feel that it is worth publishing our results (incomplete as they are) as with further work they may prove of some value to those engaged in research work and interested in the problems of the unfortunate diabetic.

By the systematic use of laxatives in diarrhoea, serious states of illness can be provoked. Only cases of a definite alimentary intoxication can offer occasionally an indication for such treatment. Just as in the most intensive state of diarrhoea we know, namely, cholera, nobody would think of giving laxatives.

On theoretical grounds Salomon and Wallace gave patients suffering from acute enteritis sweet tea and fruit juices. According to their expectations, the authors observed a rapid ceasing of diarrhoea. They expressed the opinion that they knew no better measure to stop acute diarrhoea.

Later, von Noorden and Salomon (1929) used 'marchepan' (almond powder mixed with equal parts of powdered sugar and with a little white of egg) and different kinds of fruits. They came to the conclusion: one frequently has the surprising experience that one provokes diarrhoea only if fruits and their derivatives are mixed with other food substances. The exclusive administration of fruits and fruit juices has the effect of a direct remedy.

Similar experience has been reported in the treatment of sprue, e.g., by the strawberry diet. I have now come to the conclusion that one can take without danger in diarrhoeal illnesses fruits with other aliments as long as to the latter salt is not added.

Later on, came the reports of Heisler (1928) and of Moro (1929) about the effects of the apple treatment in acute diarrhoeas.

There are numerous explanations given to the apparently paradoxical effect of exclusive fruit diet in diarrhoea (Salomon, 1936), but my own practical experience has convinced me that the effective factor, the link connecting these various observations, is the absence of salt from fruits. Since one can mix fruits with other salt-free food, with sweet soups, with sweet biscuits, etc., without damaging the effect. As soon as the acute phases of the attack have passed, puddings, *soufflés*, etc., are also harmless, that means dishes which are prepared with little milk (percentage of salt in the milk 1.5 to 1.8 grammes per litre).

I give two examples.

Case 1.—Male, aged 55 years, generally healthy, with normal blood pressure, fell ill suddenly before breakfast with pains in the abdomen on 5th May. Evacuations at first were soft, later watery with vomiting of sour mucus only. Pulse 88, soft, temperature 37.6°C.

On account of nausea and want of appetite all food including purée of apples was refused. At 11 o'clock 10 drops of tincture of opium. Up to 12 o'clock he had 8 watery dejections then the diarrhoea ceased.

At 6 p.m. a vanilla ice was taken.

6th May.—He had a quiet night. Temperature 36.8°C., some pain in the abdomen, 3 watery dejections before breakfast.

Breakfast: porridge with milk, tea with sugar, sweet bread.

Lunch: Caramel custard, jelly of wine.

Tea: Tea with sugar, confectionery.

Dinner: Cold rice boiled, with milk and sugar; compot of pears.

He had no trouble and during the day no evacuation.

7th May.—Breakfast: porridge with milk and sugar, compot of apricots, tea with sugar, sweet biscuits.

Lunch: pancakes filled with marmalade, *soufflé* of sago, apples.

Tea: Tea with sugar, confectionery.

Dinner: Barley soup, sweet *soufflé* of rice, compot of pears.

No stools, good state of health.

8th May.—Return to ordinary mixed low-salt diet. First dejection at 5 p.m., well formed, subsequently he remained in good health.

The same good results will be found in the treatment of chronic diarrhoea with salt-free diet. The following case seems to me very illustrative, as the patient was living in a hotel at Saigon where the treatment naturally was more difficult than in hospital or in a private house.

Case 2.—Male, aged 65 years, constitutionally healthy.

For some weeks, from time to time, specially after meals, he had pains in the abdomen, the dejections were soft and thin, 4 to 6 times in the 24 hours, with considerable quantity of slime. Appetite was good. By omitting vegetables, fruits and coarse bread, and using carbonate of lime 4 to 6 grammes a day, constipation and good health were attained, but returning to the ordinary diet there was a great tendency to relapse.

23rd May.—Three thin evacuations, with some mucus; pain in the bowels; appetite and general state good.

Mixed diet taken with caution.

24th May.—More colic, 4 thin dejections, state of health generally worse. Fruits and compots now omitted. Carbonate of lime 4 grammes taken.

25th May.—No change, 4 soft stools.

26th May.—Slept well: at 5 o'clock pains and soft stool.

8 a.m.: Tea with sugar, barley soup cooked with *maggi* and a little salt and butter.

10-30 a.m.: Pains and thin evacuation and later severe pains and watery dejection, with tenesmus.

Beginning of the nutrition with salt-free diet

2 p.m.: Tea with sugar.

5 p.m.: Barley water sweetened with 4 pieces of sugar.

8 p.m.: Feeling well, a glass of pineapple sorbet, 3 sweet biscuits.

Noises in the bowels, no pain.

27th May.—Good night, flatulence, but no stool.

8 a.m.: Half a tin of apricots with the juice.

11 a.m. Pea soup and the other half of the tin of apricots.

Lunch: Two mandarines, 2 mangostines, stewed pears, and pastry.

Dinner: The same as for lunch.

28th May.—No trouble; no stool, but a small quantity of slime was evacuated.

Breakfast: Tea with sugar, white bread with raspberry jam, one apple, one banana.

Lunch: Fruit tart, 2 mandarines, 2 mangostines.

Dinner: As above with a sweet omelette.

29th May.—First stool since 27th May, small quantity, well formed.

Under slow transition to a mixed diet with a moderate allowance of salt, the patient returned to good health.

During this observation it was evident that the salt-free diet influenced the state of the bowels in a more favourable manner than the salt-containing diet, although the latter was less offensive from the point of view of its cellulose content.

For carrying out a salt-free diet all our food-stuffs are suitable, because they are nearly free

INJECTION METHOD OF TREATING ENLARGED INGUINAL GLANDS IN EARLY CASES OF LYMPHOPATHIA VENEREUM (LYMPHOGRANULOMA INGUINALE)*

By MIN SEIN, M.B. (Cal.), M.R.C.P. (Lond.),
CAPTAIN, I.M.S.

Civil Surgeon, Rangoon (East) and Lecturer in
Medicine, Burma Government Medical School,
Rangoon

DURING recent years more and more cases of lymphopathia venereum (lymphogramuloma inguinale) are being diagnosed as the clinical features and tests are better understood. If left untreated, or even in treated cases, the disease can result in much suffering and disfiguring due to scarring. Of the local method of treatment chief reliance has been placed on the time-honoured belladonna and ichthyol ointment in the early stages, and fomentations and incision in later periods. The time spent in

* Note.—The nomenclature of this disease has undergone a number of changes, and until a few years ago 'lymphogramuloma inguinale' was favoured by the majority of writers. This name was unsuitable, mainly because the pathological process is essentially unlike a granuloma and the name lymphopathia venereum seems to find most favour to-day. This is the term adopted by Dr. H. S. Stannus in the *British Encyclopædia of Medical Practice*. As uniformity is advisable we have changed the title and text of this paper in accordance with modern usage.—EDITOR, I. M. G.

(Continued at foot of next page)

from salt by nature and only the milk contains a small quantity, but many dishes, for instance vegetables and soups, are not very palatable without salt. The most suitable dishes are sweet, as sugar compensates for salt in a splendid manner. Soups of oatmeal, barley, peas, lentils, etc., can all be sweetened with sugar. Fresh butter (unsalted) can be added if the state of general nutrition demands. Eggs, boiled or fried, or as an omelette, can be given, and also fruits and nuts. Soon it is possible to add sweet dishes which have been made with milk—custards, puddings, pancakes, ice-cream, tarts and confectionery.

Now on a long visit through India, I publish my views hoping that they will be useful to doctors in the treatment of cholera as well as acute and chronic dysentery.

palliative treatment can be long and in the end prove to be fruitless.

The following method is published as it has proved its worth and is simple in application. I started using this method in 1932 whilst in charge of the venereal ward in the British Military Hospital (Indian Wing), Mingaladon, in cases of venereal bubos secondary to soft or hard chancres or gonorrhoeal urethritis after the ordinary palliative methods had failed. It was also used in cases where though a history of venereal exposure was obtained clinical and laboratory examinations negated an infection by syphilis, gonorrhoea or soft sore. It was possible that some of the latter cases were cases of lymphopathia venereum. Since then fairly typical cases have been similarly treated with success and the treatment has been extended to cases of bubo due to venereal diseases.

The method

The method consists in the injection of a few minims of equal parts of liquid carbolic acid and absolute alcohol into the enlarged glands. A fine hypodermic needle is selected and the syringe filled with the solution. After the skin has been sterilized with methylated spirit it is stretched and the needle is inserted some distance from the gland; it is then pushed obliquely into the centre of the enlarged gland. After seeing that it is not in a blood vessel the solution is injected. It is advisable to push in a few minims of air to empty the needle otherwise carbolic acid is likely to be left along the track of the needle and slight pain might result. Frequently, a small depressed black spot will mark the site of injection. No pain is felt and improvement in signs and symptoms will be noticed within 24 hours. The enlarged and painful gland will generally subside without proceeding on to suppuration. It may be necessary to give more injections into the same or other enlarged glands after two or three days' interval. The above method is not meant for cases where there is definite softening and commencing suppuration but is useful where the glands are painful and enlarged.

I have treated several cases by this method but a typical case is described below.

A Burmese police constable, aged 22, was admitted to Bhamo Civil Hospital on the 16th May, 1935, on account of hard and painful glands in the left inguinal region. He had developed a small sore on the penis after exposure and this healed up in four days. He had a temperature of 100°F. He was treated with belladonna and ichthyol ointment and tincture of iodine intravenously. There was no improvement, but on the other hand the glands on the right side also became enlarged and tender in spite of applications of antiphlogistine. Carbolic acid solution was injected into the glands on four occasions, on the 21st June, 27th June (two areas), 1st July (two lower glands), 8th July (other glands). Improvement was rapid and sustained and the patient was discharged cured on the 10th July, 1935. He was examined again in November 1935 when the cure was found to have been sustained. The Wassermann reaction was negative.

ON THE EFFICACY OF THE GONADOTROPIC HORMONES IN THE TREATMENT OF WHOOPING COUGH

By K. VENKATACHALAM

and

A. N. RATNAGIRISWARAN

From the Medical College, Madras

It is characteristic of whooping cough that its incidence is confined chiefly to children below 10 years of age, though occasionally it has also been reported in old people. Persons above the age of 10 and right through healthy adult life are generally immune to the disease, in spite of living in intimate contact with infected children, even though they might not have been attacked previously by any disease having the vaguest semblance of whooping cough. Second attacks in children have also been recorded though only rarely. Further, the vaccines prepared from the organisms isolated from the droplets or the upper respiratory passages of infected children have not been as effective therapeutically as they ought to be if the disease were caused only by infection.

These considerations suggested that, besides any immunity that might have been acquired, there is some other factor which is peculiar only to the period of life between the age of 10 and the end of the adult age that determines the power to resist an attack of whooping cough during this period. One of the dominant features of life at this stage is the activity of the sex glands, and the assumption that the immunity displayed is associated with such activity would be justified, if it could be demonstrated by any means that a temporary stimulation of the activity of the gonads in persons of the susceptible age would act as a curative, as well as a prophylactic, agent. Results of the clinical trials carried out so far have provided sufficient evidence for the correctness of this view.

In the clinical investigation reported in this paper, the stimulation of the gonads was effected either by the oral administration of a standardized preparation of the gonadotropic hormones of pregnancy urine which is described in detail below, or by the injection of Antuitrin 'S'. The latter could not be tried as a routine measure on account of the prohibitive cost and was resorted to only when the oral medication had been ineffective.

*(Continued from previous page)**Summary*

A method of treating enlarged glands in lymphopathia venereum (lymphogranuloma inguinale) as well as in other venereal conditions is described in which 50 per cent carbolic acid in absolute alcohol is injected into them.

A case is described.

The standardized preparation of the hormones for oral administration was prepared in this laboratory by a modification of the method of Davy (1934). Pregnancy urine was acidified with glacial acetic acid to a pH 5 using brom-cresol-green as the indicator. The urine was centrifuged or filtered if it did not become clear by centrifugalization. To every litre of the clear urine 10 g. of active charcoal was added and the mixtures shaken continuously in a mechanical shaker for eight hours. The pH was again adjusted to 5 and the charcoal containing the adsorbed hormones was filtered under suction on a hardened filter paper moistened with 1 per cent acetic acid. It was washed well with water till the wash water was neutral to litmus, dried, and stored in a vacuum desiccator at a temperature of 15°C.

The activity of the preparation was tested in each case by the usual biological method using 13 days old, immature, female white rats as the test animals. The rats were selected from a litter in which the animals attained sexual maturity 40 to 50 days from the day of birth. The charcoal adsorbate suspended in distilled water was poured down the throat of the animal by means of a fine pipette. Based on our findings, a rat unit was taken as the minimum amount of the product which produced opening of the vagina and œstrus on the seventeenth day of age, when administered orally in eight equal doses during four consecutive days. One rat unit was contained in 10 milligrams of the preparation.

Five hundred to nine hundred rat units, the exact requirement depending upon the virulence of the disease and the individual variations, were usually found sufficient to alleviate the characteristic symptoms. Where parenteral administration was indicated, 0.25 c.cm. of Antuitrin 'S' was injected daily. After six to twelve injections, the vomiting and the whooping stopped completely. The residual cough was treated symptomatically. The criterion of cure applied was the total disappearance of the whoops and vomiting and a diminution of the cough.

All the cases reported herein were treated under our personal supervision and guidance.

A perusal of the table will show that in all the cases the blood picture had been typical. There was a marked leucocytosis of 12,000 to 30,000 per c.mm. with 46 to 76 per cent of lymphocytes. Twenty cases out of the 23, or 87 per cent, were cured by oral treatment with the hormones or by injection of Antuitrin 'S'; in three cases, or 13 per cent, either treatment failed. The proportion of probable cures to failures in this series is 5.1:1. In the therapeutic doses prescribed, the preparation of the hormones did not produce any undesirable symptoms.

No case of whooping cough in old age has come to our notice so far.

The administration of the hormones as a prophylactic measure to contacts conferred immunity on them.

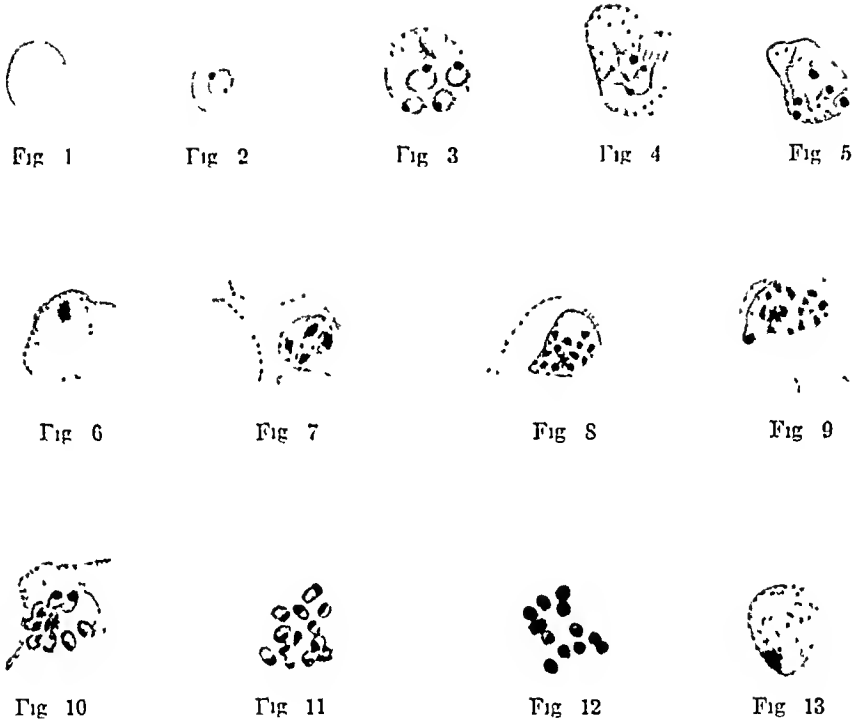

In another series of 113 cases which were treated by qualified allopathic medical

SOME ANOMALIES IN THE MORPHOLOGY OF *PLASMODIUM VIVAX* OCCURRING IN A NEWBORN BABY

By B. M. DAS GUPTA

From the Calcutta School of Tropical Medicine

THE material on which the following observations were based consists of a single blood smear

(Continued from previous page)

practitioners in the city and the *mofussil*, 70 cases were reported to have derived benefit by the oral medication and 13 more by the injection of Antuitrin 'S', as judged by the alleviation of the distressing symptoms such as whooping, vomiting and cough. Blood examination could not be carried out in those cases for lack of laboratory facilities. The percentage of cures in this series works out to 73.5 per cent.

For the whole series of 136 cases which have been treated with the gonadotropic hormones of pregnancy urine, the percentage of cures effected is 80.3.

In cases where treatment by the parenteral route was called for, the failure of the oral method was probably due to a co-existing gastrointestinal disturbance that might have interfered with the absorption of the hormones. In the other cases which were resistant to either form of treatment, the cause of the failure might have been an imbalance of the endocrines preventing the gonadotropic hormones from exerting their usual effects. Also in those rare cases where adults have been reported to have been victims of whooping cough a possible explanation is the malfunction or dysfunction of the gonads.

The relief from the most distressing symptoms of whooping cough effected in such a short time as about a week, by the administration of the gonadotropic hormones appears to warrant the conclusion that in these hormones has been found a useful and unsuspected remedy for combating the harassing disease.

Summary

On the ground that whooping cough is a disease that shows a preference for attacking children below 10 years of age, and old persons occasionally, and that adults are invariably immune to it, it was considered probable that the power to resist and overcome the disease might be closely associated with the activity of the sex glands, the dominant feature of adult life. Based on this assumption, treatment with a charcoal adsorbate of the gonadotropic hormones of pregnancy urine or with Antuitrin 'S' was carried out in a series of 136 children and yielded satisfactory results in 80.3 per cent of the cases. The drug was also found to be effective as a prophylactic remedy.

Davy, L. (1934). *Endocrinology*, Vol. XVIII, p. 1.

taken from an infant 15 hours after birth. There was evidence of anaemia in the smear. Infection was quite heavy, so it was possible to study a large number of parasites in various stages of development. The infected corpuscles were enlarged, pale and showed marked pink stippling. Many cells were distorted, some showing fimbriated margins. Multiple infections of the corpuscle were not infrequent, and as many as five parasites occurred in one cell. In some ring forms the chromatin appeared as two dots, one much finer than the other. This type of chromatin is frequently encountered in the ring forms of *Plasmodium knowlesi* in *Silenus rhesus* monkeys, specially when the infection is very intense. Various stages of schizogony and a few gametocytes were present. Growing trophozoites exhibited marked amoeboid activity, although some were quite compact. The most striking feature was the number of merozoites produced by the schizonts. About a dozen fully-developed schizonts were examined, in none of which did the number of merozoites exceed twelve. The cells containing these schizonts were abundantly stippled.

Comments.—At first sight I felt tempted to believe that the infant had been infected with *Plasmodium ovale* Stephens, 1922, because some of the forms present in the smear, especially figures 7 to 10, bore a striking resemblance to those of *P. ovale*. But in view of the facts stated below my impression is that the infecting organism was *P. vivax* with some aberration in its morphological characters, an observation to which attention has been drawn from time to time by various observers. Thus, Missiroli and Siniscalchi (1929) studied morphological changes in a strain of *P. vivax* up to its sixth passage by direct blood inoculation. They examined the blood films of all the patients infected with this strain and noted that in some films the parasites were typical of *P. vivax*, in some parasites resembling *tenue* type of *P. falciparum*, while in others parasites resembling some stages of *P. ovale* were present. Plehn (1925) made similar observations as regards forms resembling *P. ovale*. Observations of the same kind have also been recorded in particular cases of naturally acquired infection. For example, James (1920) found that in some old-standing cases of benign tertian infection, acquired during the war, full-grown schizonts contained only 10 to 12 'young parasites'. Moreover, the red cells in which they lay, although they were profusely spotted with Schüffner's dots, were only slightly enlarged.

Wenyon (1926) while discussing the doubtful species or abnormal forms of human malaria parasites observed 'It cannot be too forcibly emphasized that the parasites of malaria like all other living organisms are liable to occur occasionally in abnormal forms, and that more evidence than the mere casual appearance of these is required before new species are created'.

The fact that the mother's blood during pregnancy showed definite benign tertian infection, as reported by Dr. Baird who was in charge of the patient, also tends to support the impression of the present writer that the stages of the parasite resembling *P. ovale* are in reality an unusual form of *P. vivax*.

Dr. Wenyon who also very kindly examined this specimen was non-committal with regard to the unusually small number of merozoites, but suggested that the unusual situation of the host (mother's womb), or the anæmic condition of its blood, might have influenced the development in some way. He further observed that if the morphology of the parasite after the inoculation into a new host remained constant there might be some reason for considering it to be a variety of *P. vivax*.

From time to time many reports have been published regarding the possibility of congenital malaria. As the parasites may be directly inoculated from the mother to the child as a result of abrasions occurring during labour and as the chances of natural infection cannot be ruled out in cases in which the parasites are found any time after birth beyond the usual incubation period of malaria, especially in localities where the disease is prevalent, critics are inclined to doubt the authenticity of the reports of congenital malaria based on mere finding of the parasites in the blood of the newly-born infants. Lately, however, Garcia (1938) reported two cases of intra-uterine infection. In one case schizonts of *P. falciparum* were found in the bone marrow, heart blood, and in other situations of a four-month fœtus found *in situ* in the womb of its mother who died of malignant tertian malaria. The demonstration of a large number of parasites in various stages of development up to maturity in our case is also highly significant, in that it proves beyond any doubt that the infection was acquired some time previous to labour.

I wish to make acknowledgment to Professor C. Strickland for securing the slide in question and to Dr. Baird of Bhagatpur Tea Estate (Dooars), who was in charge of the patient for supplying me with some information given in this paper. I am also under great obligation to Dr. C. M. Wenyon, F.R.S., for his valuable suggestions.

VITAMIN C IN PULMONARY TUBERCULOSIS

By I. BAKHSH, M.D. (Lond.), M.R.C.P. (Lond)
CAPTAIN, I.M.S.

Professor of Pharmacology and Therapeutics, K. E. Medical College and Physician to Out-Patients, Mayo Hospital, Lahore
and

Demonstrator in the Department of Pharmacology and Therapeutics and M. O., T. B. Out-Patients, Mayo Hospital, Lahore

HASSELBACH (1936) in Switzerland recommended the use of vitamin C in cases of pulmonary tuberculosis deficient in this vitamin. He obtained favourable results in certain forms of pulmonary hæmorrhage, and advocated it as a tonic in sufferers from pulmonary tuberculosis.

A year later, Petter (1937) in America published a report on 49 adults and 21 children treated by him with calcium phosphate in milk and 150 mg. of vitamin C by mouth daily. Thirty or 61 per cent. of the adults were definitely improved, 12 were unaffected and 7 were definitely worse. In the children he also noted improvement in weight and general condition. Tests for vitamin-C excretion in urine showed decreased elimination of the vitamin in advanced cases.

Shortly afterwards, Borsalino (1937) published his observations on the therapeutic value of vitamin C in tuberculosis. He found that injections of vitamin C increased the resistance of capillaries in this disease. This increase progressed for the first 12 hours after the injection, then it diminished slowly till it was the same after 24 hours. In his opinion vitamin C had a favourable symptomatic effect by which the general condition and appetite of the patients were improved and the fever and quantity of sputum were favourably modified. The anatomic condition of the lungs was unchanged. He also found that actual hæmoptysis stopped after injection, but reappeared on stopping the treatment.

Radford and her colleagues (1937) tried vitamin C in cases of advanced and fibroid tuberculosis. They gave no other therapy except routine rest, and obtained encouraging results as judged by red cell count, hæmoglobin, lymphocytes, monocyte-lymphocyte ratio and neutrophil-lymphocyte ratio. According to these observers the improvement in the hæmoglobin and red cell figures indicates a possible hæmatinic effect.

Heise and Martin (1936), however, do not agree with the above findings. They injected tubercle bacilli (300,000) into the groin of guinea-pigs on normal diet and in those receiving 20 mg. of vitamin C intra-abdominally. Their results did not demonstrate any support for excessive administration of vitamin C in tuberculosis. An obvious objection to their experiments was the large number of bacilli

introduced into an animal like the guinea-pig which has little resistance against tuberculosis; secondly, the number of animals used in their experiments was too small.

Martin and Heise (1937) later tried the effects of vitamin C in pulmonary tuberculosis on a series of cases. Again they did not obtain any evidence of the effect of vitamin-C therapy on the course of pulmonary tuberculosis, as judged by ray, sputum examination, sedimentation rate, and tuberculin skin tests. They also noted that intravenous vitamin C failed to stop the hæmorrhages in tuberculous patients. The authors believed that vitamin C does improve the prognosis in pulmonary tuberculosis but no definite evidence was obtained for this impression.

More recently, Hurford (1938) has tried the effects of vitamin-C therapy in pulmonary tuberculosis in England. In a series of 66 cases he found 64 per cent of the patients to be suffering from hypovitaminosis, taking the minimum normal limit of vitamin-C excretion in the urine as 14 milligrammes. This observer found no constant relationship between vitamin-C excretion and the sedimentation rate, von Bonsdorff count, or the extent of the disease. Of the 42 patients treated with this vitamin only 7 showed any significant improvement and these patients were suffering from microcytic anaemia.

From the above it is clear that vitamin-C excretion is greatly decreased in the majority of cases of pulmonary tuberculosis and there is uniformity of opinion among workers all over the world on this point. But there is no agreement on the question whether vitamin C has any influence on the clinical condition in pulmonary tuberculosis, as is shown by the conflicting reports. In this country we are not aware of any published work on this subject. One of us (I. B.) has been using large doses of vitamin C in his private cases with variable results. It is, however, extremely difficult to assess the value of this remedy in this way as these patients were receiving other forms of treatment at the same time.

The present confusion about the value of vitamin-C therapy in tuberculosis prompted us to try it on a controlled series of cases in the tuberculosis wards of Mayo Hospital, Lahore.

In selecting our cases the following points were kept in view. Realizing that the standard of nutrition of the majority of cases admitted into the general wards of this hospital is below normal, all the selected cases had been kept for a sufficiently long period in hospital to correct any gross dietary deficiency and to exclude the apparent effects of rest in bed. As a rule only early cases with sufficient chances of recovery are admitted into the tuberculosis wards of this hospital, so that none of the patients were suffering from advanced disease. Furthermore, only those cases were selected who had not improved on the usual lines of treatment, such

as rest in bed, cod-liver oil, gold injections and artificial pneumothorax, or else those in whom gold therapy and pneumothorax had been considered unsuitable.

Of the 24 cases thus selected, 19 showed deficient excretion of vitamin C in the urine, as estimated by the method of Harris and Ray (1935). With the exception of one case who excreted only 4 milligrammes in 24 hours, the figures were between 10 and 16 milligrammes. No. 6 excreted 55 milligrammes in 24 hours but was included in the series because he looked very weak, pale and ill-nourished. Fourteen cases had unilateral lesions and in 6 both the lungs were affected. With the exception of one case of chronic fibroid tuberculosis the rest were all of the mixed exudative type. Three cases gave a history of hæmoptysis during the onset of the disease.

All the patients were given 150 to 200 milligrammes of vitamin C in tablet form by mouth daily over a period of six weeks. In addition every case received 500 milligrammes of the vitamin daily by intramuscular injection for four days during the first week of treatment. As tuberculous patients are very suggestible, due precautions were taken to administer the preparation in a casual way and to avoid the impression that they were getting a new and important drug.

The points noted were the patients' own feelings of well-being, appetite, weight, cough, expectoration, temperature, changes in hæmoglobin, red cell counts, and sedimentation rates, together with clinical examination of the lungs at weekly intervals.

Three patients left the hospital of their own accord during the early part of the treatment as their condition deteriorated greatly. One of these, a female with a history of previous hæmoptysis, who was receiving 200 milligrammes of vitamin C daily, developed a severe attack of pulmonary hæmorrhage which could not be controlled by any means including injections of vitamin C. She was removed from the hospital in a moribund condition by her relatives.

The result of six weeks' treatment with vitamin C in the remaining 17 cases is given in the following table.

As will be seen from the table the appetite was favourably affected in two cases only. The increase in weight, however, occurred in ten patients, this ranged from one pound in four cases to 21 pounds in five and 3 in one case. The weight in two cases remained stationary, five patients lost weight varying from 1 to 4 pounds, while one lost 8 pounds. The two patients who showed improved appetite gained 3 pounds and 1 pound respectively.

The cough, as reported by the patients, was lessened in 8 cases, in 1 it was increased, and in the remaining 8 it was uninfluenced. The expectoration, however, was decreased in only 3 cases in which the cough was diminished.

Tabular summary of results

Case number	Vitamin C excretion in urine in mgm.	Appetite and feeling of well-being	WEIGHT IN L.B.		Cough	Expectoration	Temperature	RED BLOOD CELL COUNT IN 10 ⁶ PER C.M.M.		HÆMOGLOBIN PERCENTAGE		SEDIMENTATION RATE

* There was no cough or expectoration before.

† Developed hæmoptysis stopped by A.P.

‡ Condition became worse and patient left.

§ Developed severe hæmoptysis which could not be controlled, and the patient was taken home.

|| Left the hospital.

An interesting point, which was also noted previously by one of us (I. B.) in his private cases, was the initial rise of temperature, whether the vitamin was given by mouth or parenterally. In the present series ten patients showed rises of temperature varying from 1°F. to 3°F. which lasted for 3 to 4 days. It is difficult to give any explanation for this phenomenon, and we are not aware of any reference to this point in the literature. It is apparently seen only in cases of pulmonary tuberculosis for in most other diseases in which the same brand of vitamin C was used no appreciable rise in temperature was observed.

The hæmatological findings were more favourably influenced. Thirteen cases showed an increase in the total red cell counts, ranging from 100,000 to the maximum of 3,000,000 cells per c.mm. The rise in hæmoglobin, however, did not go parallel with the increase in the number of red cells. In most cases in which the red cells were increased the hæmoglobin percentage remained stationary. In two cases it fell by 10 per cent although the red cells had increased by 200,000 and 800,000 per c.mm. respectively. In spite of the danger of forming any definite conclusions from such a small series of cases we are tempted to attribute the blood changes to a specific effect of vitamin C on the red cell manufacturing function of the bone-marrow.

In eleven cases the sedimentation rate was appreciably reduced, the maximum reduction being 64 and 41 mm. in cases 7 and 3 respectively. This favourable effect on the sedimentation rate went parallel with the improvement in cough in most cases, but it had no relationship to the changes in the red cell counts. For instance, in all the cases in which the sedimentation rate was lowered the red cells were increased. In case no. 4 which showed an increase of 9 mm. the red cell count was raised by 1,700,000 cells per c.mm. and in case 11 the red cells were increased by 1,200,000, although the sedimentation rate went up by 50 mm.

Whether the reduction in the sedimentation rate is due entirely to the beneficial effects of vitamin C, we are not in a position to give our definite opinion. The present work was started in the second week of August when the maximum temperature in Lahore is often above 110°F., and by the beginning of October it had fallen by 10° to 15°. It is therefore difficult to rule out the influence of external temperature on the sedimentation rate in these cases.

Of the three cases out of 20 with past histories of hæmoptysis two developed it again during the course of vitamin-C treatment. In both patients vitamin-C injections failed to control the hæmorrhage, one left the hospital

of her own accord and the other responded to artificial pneumothorax.

As regards anatomical changes in the lungs, as judged by clinical examination and x-ray, no appreciable change was detected in any of the cases.

Conclusions

Although we feel that the number of cases investigated by us is too small to form any definite opinion about the value of vitamin C in pulmonary tuberculosis, the observations as recorded above may be of some value in stimulating further research in this country. In a disease like tuberculosis for which we possess no specific remedy, more than one therapeutic agent is usually necessary. Vitamin C is far from a specific remedy in this disease, but from the impression formed from a limited number of cases observed by us we are of opinion that—

- (1) Vitamin C is a valuable adjuvant to other forms of treatment in pulmonary tuberculosis where it is deficient.
- (2) Its therapeutic value is most marked when there is co-existing secondary anaemia.
- (3) Vitamin C has little effect on appetite although the weight is favourably influenced in the majority of cases. The cough is lessened in nearly half the cases but the expectoration is not influenced much.
- (4) The sedimentation rate is lowered in more than half the cases.
- (5) The temperature and physical signs in the lungs are not influenced.

Our thanks are due to Mr. B. D. Kochhar, M.Sc., chemist in the department of pharmacology and therapeutics, K. E. Medical College, Lahore, for testing vitamin C in the urine, and to Col. G. G. Jolly, C.I.E., V.H.S., I.M.S., Inspector-General of Civil Hospitals, Punjab, for permission to publish this paper.

[The expenses of this research were partly defrayed by a grant from the B. M. A. Punjab Branch to one of us (I. B.). We also thank Messrs. Merck & Co. for free supplies of their preparations 'Cebion' and the dye, 2:6 dichlor-phenolindo-phenol].

EVOLUTION OF GOLD THERAPY IN PHTHISIS

PART I

By S. K. DAS, M.B.

Visiting Physician, Islamia Hospital, Calcutta

The promising results obtained from the use of gold in the treatment of tuberculosis by different observers should give an impetus to the desire for further knowledge on the subject.

The actual date of its first application might be traced centuries back. Hopes and disappointments have come in their way, but the world-wide search for a cure for tuberculosis has gone on through the centuries.

Gold salts came into use many centuries before Christ, for in ancient Hindu medicine the preparation 'Makaradhwaja' was supposed to be a specific against tuberculosis and various (almost all) other diseases. Abu Moussa the Wise recommended the use of gold as a cure for all diseases. His findings can be traced back to the eighth century A.D. But it was not until about 1500 A.D. that we find it used as a specific for tuberculosis, when Paracelsus, the alchemist and chemist, used a compound of gold and mercury and called it the 'elixir of life'. Unfortunately, his experiments met with disasters and its use was dropped for a long time, and it seems that scientists gave up the idea altogether for a time. It was not until over three hundred years later that the therapy was revived by Chrestien (White, 1894).

It was about this time that a real advancement was made towards the therapeutic effects of gold when Robert Koch (1890) reported his valuable laboratory findings, and began his experiments with the cyanide of gold. His laboratory findings were very encouraging and he showed that a dilution of 1 in 3,000,000 of gold cyanide was enough completely to inhibit the growth of tubercle bacilli. He carried on his experiments on animals but found that in the animal body the salt was useless. An explanation to this fact was not possible till 1915 when Shumacher published an article proving that gold cyanide would dissociate at once in the animal body in the following way :—

The free gold ions and the cyanide group would inhibit the growth of tubercle bacilli in the test tube.

Returning to our chronological table we find that in 1891 J. B. White for the first time reported successes from the use of a complex compound of a double chloride of gold and sodium combined with manganese iodide. This treatment was a success as could be judged by

the facts that it (1) prolonged animal life including that of human beings, (2) improved appetite, (3) produced a distinct gain in weight, (4) diminished cough and sputum, (5) helped absorption of abnormal deposits, as evidenced by the disappearance of râles, and (6) improved blood conditions.

These and various other improvements, notably that of Gibbes and Shurley, who carried out a combined iodine treatment with gold, gave an impetus for further research on the subject.

Between 1912-1915 extensive researches were carried on by German workers some of whom reported favourable results with gold potassium cyanide, notably in skin tuberculosis. Some of them contended that the fatty envelope of the tubercle bacilli was difficult to penetrate and a solvent for the sheath might give good results, and they tried chemicals like borholin for the purpose. In 1917 Oberstadt reported favourable results, but no case of complete recovery, if gold was combined with tuberculin.

Favourable results were also obtained by Bettman and Junker both in pulmonary and skin tuberculosis.

A further step was made when Bruck and Glück in 1913 after a series of unsuccessful experiments suggested intravenous administration, and Rosenthal (1913) claimed good results by the injection of tricyanide of gold directly into the diseased area.

Success was claimed in skin tuberculosis with gold potassium cyanide by Poor and Geber.

Further researches were carried out on the subject between 1912-1916 by Shies and Feldt, who began experiments with both gold cyanide and gold potassium cyanide. They totally denied all claims of success from the use of these products and thought that a drug of such high toxicity should not be used in animal experiments. They argued that if gold could be combined with some substance that might have some affinity for tubercle bacilli the drug might be used in concentrations that were harmless to the human body. They tried cantharidine which, if it could be made less toxic and yet easily compoundable with gold, would serve their purpose. They detoxicated cantharidine by combining it with ethylenediamine and found that it was compoundable with the cyanide of auric salts. But they found that the product was much less efficacious, so they replaced the auric by an aurous salt and found that it was 100 to 1,000 times more efficacious. The result was mono-cantharidyl-ethylene-diamine-aurous cyanide, which they called 'Auro-cantan'. The formula was

This product was a great success; it was supposed to act both by a direct action on the tubercle bacilli as well as by increasing the defensive mechanism of the body. Post-mortem study in experimental animals, where intravenous administration was possible, showed that lesions tended to be more productive in character and tubercles tended to disappear. Clinically, life was prolonged and there was distinct gain in weight. Failure in long-continued subcutaneous administration was supposed to be due to tissue necrosis and development of gold tolerance of the tubercle bacilli which was proved by finding that, after one and a half months, the bacilli would grow and thrive in 1 in 400,000 solution of gold cyanide in agar, whereas to start with they would not grow in 1 in 2,000,000.

Paul Ehrlich showed that the inorganic salts were less useful and more toxic and so he suggested organic gold therapy by combining gold with carbon which however was not a practically stable compound.

Further improvement, notably that of Feldt, was made; he recommended a product called 'Krysolgan' which is the sodium salt of p-amino-o-aur-phenol-carbonic acid, having the

formula and whose action was favourable and comparable to tuberculin.

Reviewing the progress of gold therapy which went on for centuries, we should stamp the researches of Möllgaard as a distinct advance. In 1924 he published a paper in which he described his search for an ideal preparation that would be (1) bactericidal to tubercle bacilli, (2) highly soluble in water, (3) readily diffusible through the body tissues, and (4) without any toxic effect, especially on the liver and the kidneys.

This was crowned with success when he produced a gold salt with sodium thiosulphate having the formula :—

This he called 'Sanocrysin'. This salt is almost identical with another product that was discovered by two French chemists, Fordos and Gelis, in 1846. It has two molecules of water more than in the former preparation. The formula might be given as

and this they called 'Crisalbine'; on analysis it yielded 37 per cent of gold and 24 per cent of

sulphur. 'Crisalbine' is available in India and is manufactured in England. It satisfies all the conditions required of such a preparation, if judiciously administered.

The difficulties connected with this preparation are that it has to be administered intravenously and so might be unsuitable for administration in young children and in those with not very prominent veins. Moreover, some people do not like to administer heavy metals by the intravenous route and prefer preparations that can be administered intramuscularly.

A solution to this problem was found in the preparation Myocrisin which is sodium thiomalate of gold having the formula:

It contains 50 per cent of gold.

Experiments with 'auro-etu-chloride' having proved bacterio-inhibitory power *in vitro* has now reached the stage of clinical trial where it has proved to be well tolerated in patients and is sufficiently encouraging in results to justify a more extended trial' (Twenty-fourth annual report of the King Edward VII Welsh National Memorial Association, 1936).

We can thus in brief conclude our history of gold therapy up to date and pass on to other details.

Mode of action

Gold has no specific action on tuberculosis alone since any inflamed connective tissue has the power to fix gold salts (Henius) and the action on tuberculous granulation tissue is similar to this. Schröder points out that every inflamed tissue reacts similarly to gold salts.

In the course of our discussion we have explained how scientists have tried to find a specific for tuberculosis. Gold has been described as having a direct bactericidal action on tubercle bacilli. Gerlach, Koppenhöfer, Feldt and others have tried to prove a specific action on tubercle bacilli and some have been able to demonstrate by histological study and by spectroscopic examination the selective abundance of gold in tuberculous foci. Their argument has been that gold forms a soluble gold protein compound with the bacilli and thus kills them. But this claim has been disputed (Schröder) and no one has been able to show successfully that it can kill tubercle bacilli in the human body. This is borne out by its having no effect on any tuberculous lesions in the body except pulmonary ones (Wingfield).

The second explanation of the mode of action of this drug—as a general tonic to the whole system by improving appetite, diminishing cough

and sputum, and thus increasing weight and prolonging life—is unquestionable, but this also does not give us any true idea as to its real mode of action.

The best explanation that has been put forward is that it stimulates the cells of the reticulo-endothelial system, especially those in the endothelial lining of the capillaries and blood vessels, as occurs in non-specific protein therapy. These cells, stimulated by gold in colloidal form, are thrown into the circulation in large numbers and are arrested in the congested lung area where capillaries are in abundance and where circulation is sluggish. These cells permeate the walls of the capillaries and engulf the bacilli and the waste products, and also help fibrosis and indirectly calcification at a later stage. The action of gold on the endothelium is of a toxic nature (Heubner). Wells contradicts the theory as absurd but believes that its mode of action is similar to that of a 'catalyst' which helps autolysis of the tubercles and the effect on the tubercle bacilli is of an indirect nature. But gold in colloidal form has been demonstrated as having penetrated the cells of the reticulo-endothelial system and the latter have been seen to have engulfed the mycobacteria, cell debris, and waste products.

It has also been pointed out by Feldt and Schott, Kirtschewsky and others that the mesenchymal cells as well as the fibrous components are stimulated into activity by the catalysing agency of the gold salts, which can be demonstrated in a histological section. So, we can state that the most modern idea about the action of gold on tuberculosis is that it is of the nature of a catalyst which, by liberating the cells of the reticulo-endothelial system and the mesenchymal fibrous tissues, sets the defensive mechanism of the body into action and also accelerates the spontaneous healing process (Feldt).

Rationale of the use of gold salts.—Koch and various other investigators found very little beneficial effects, if any, with the use of gold salts in tuberculous animals.

Pekanovich and Hauck (1913-14) stamped it as a dangerous drug as it caused (1) a severe hæmorrhage, (2) anæmia and (3) hæmolytic jaundice.

Galpe experimented upon cats and dogs, and described its toxic effects on the capillaries as it caused hæmorrhage into the lung alveoli within a few minutes.

Feldt pointed out that the bacilli developed tolerance to gold salts *in vitro* and so they could not produce any good effect, but this has been contradicted by Shiga (1916) and Wells, deWitt and Long (1923) in their experiments stated that the development of tolerance was so slow that it could not materially hamper the treatment.

Whether gold can stimulate the activity of tubercle bacilli in concentration less than is

sufficient for their destruction is a controversial point and many people have described it as a double-edged sword. Gold cyanides and cantharidyl-ethylene-diamine-aurous-cyanide, recommended by Spiess and Feldt, were tried with controls, and life was found to be cut short and the disease increased. It has been contended that tubercle bacilli have been found to thrive in organs such as the lung, spleen, liver and kidney which have been impregnated with a lethal dose of gold and the explanation has been given as follows:—

- (1) This gold salt on entering the body dissociates into gold and the acid radical. The gold ion combines into a gold-protein compound and is found in a colloidal state which is without any action against tubercle bacilli. This explanation is contrary to what Feldt showed—colloidal-gold-asparagin compound is inhibitory to the growth of tubercle bacilli and is almost equivalent to gold tricyanide.
- (2) The bacilli might be located in strategic positions that are not accessible to gold. This seems ridiculous as the bacilli must get nutrition and any imaginary crypts and crevices seem unlikely.
- (3) The cell membrane might act as a protective shield to the organism; this is also open to question.
- (4) The old controversial question of gold tolerance might be a factor.

Sanoerysin was described as a drug the value of which as a specific for pulmonary tuberculosis was undoubted, but as regards its by-effects it was stated that the drug, if used in the proper way, and in proper dosage was without any ill effects in the non-tuberculous subject, but in the tuberculous subject and when a correct dose has not been given it would be attended with severe toxic effects which would be manifest in the following symptoms:— (a) shock and collapse, (b) dyspnoea and cyanosis, (c) pyrexia, (d) toxic nephritis, which was proteotoxic in nature and not due to heavy-metal poisoning, as in that case the non-tuberculous subject's kidney would not have been exempt.

This is not a reasonable idea as the direct action of the drug on tubercle bacilli has never been established, because in that case the extra-pulmonary lesions would have been equally benefited.

Extensive trials with the first batch of drugs were carried out and the results have been too appalling to quote. 'The only conclusion that could be drawn from this trial was that Sanoerysin was a dangerous and highly poisonous drug which certainly had some direct action on pulmonary tubercular lesions' (Wingfield).

Some people in London and others elsewhere thought that the drug was directly bactericidal

and by killing the bacilli much toxin was thrown into the circulation; so they tried an antitoxic serum which would counteract the ill effects, but this serum proved worse than useless. This again we can attribute to a wrong selection of cases and indiscriminate use of haphazard dosage.

Reports from careful observers, notably those of Gravessen in Denmark and Heaf in England, speak very highly of the therapy and in their opinion two things are of the greatest importance, namely, choice of case and proper dosage.

In their opinion the drug has no effect on the proliferative or fibro-caseous types of tuberculosis, but if the body resistance be good early exudative types tend rapidly to clear up.

Gravessen showed with x-ray a record of successful cases where early exudative lesions disappeared with gold therapy. Jacqueroed showed that the same results could be obtained with prolonged sanatorium treatment alone.

Morland and Wingfield established the fact that, with proper individualization of dosage, it was a harmless drug or at least by no means alarming, but perpetual vigilance is required in the course of its administration. Their experiments with some of the more advanced types of cases, where the lesions were fibro-caseous or semi-productive in nature, proved to be unexpectedly successful. Out of 30 cases 17 showed striking improvement.

The effect of gold on early soft infiltration has uniformly found favour with authorities all over the world: Möllgaard and Gravessen in Denmark, Heaf in England, J. Zinkernagel and G. Schröder in Germany, Fordos, Gelis and P. Ameuille in France. Oberstadt in America, Shiga and Somogyi in Japan, Lenard in Hungary, M. Lucchesi in Italy, are among those who have had good results.

Personal experience.—Das (1936) published good reports on a batch of cases with their x-ray findings, and he considers that, if we can make a proper selection of cases and if the dose be graduated according to age, body weight, and general condition, if proper distinction between Europeans and Indians, males and females, and the types of lesion (perhaps the all-important factor) is made, and keen observation kept on the progress of the disease, if the results are checked from time to time by x-ray examination, if proper attention is paid to improving general condition by feeding and personal hygiene, improving general hygienic surroundings including the disposal of sputum (the patient being told not to swallow the sputum and not to spit indiscriminately), to sanatorium principles of exercise, care-free rest to body, mind, and voice, etc., and if in women stress and strain of life and child bearing in particular be carefully avoided, there is no reason for failure of this form of therapy. In fact, my experience with the drug has been

uniformly encouraging and no disasters have occurred so far.

Pharmacology.—Sodium thiosulphate of gold (Crisalbine) is an organic salt whose chemical composition has already been referred to. It is in the form of silky white crystals, readily soluble in water forming a clear, transparent neutral solution. On analysis it yields 37 per cent of gold and 24 per cent of sulphur. When dry, it forms a very stable preparation, but in solution or when moist it will not keep for long. Given intravenously in a solution that is isotonic with the blood serum (4.5 and 5 per cent), it is an ideal preparation as it satisfies all the conditions required of such a preparation: to repeat—(1) it is readily soluble in water, (2) readily diffusible into the tissues, (3) does not produce any toxic effect if judiciously given, and (4) is claimed to be bactericidal to tubercle bacilli.

Intravenous administration of Crisalbine being imperative another equally efficient preparation for the intramuscular route was tried and we find a very satisfactory preparation in Myocrisin.

Myocrisin is available in two forms—one the water-soluble form for injection intramuscularly in aqueous solution and the other in oil—the latter I prefer. The salt occurs in fine pale-yellow crystals—readily soluble in water and is very stable. The oily preparation is a thick milky-white substance which may stick to the glass of the ampoule but it has been provided with glass beads and on moderate shaking or warming a homogeneous suspension is formed which is easy to inject intramuscularly and the operation is painless. Both these varieties have a constant gold content and yield 50 per cent of gold.

Though some people prefer the ordinary variety on account of the ease of administration of the aqueous solution, the advantages of the oily preparation over the aqueous solution (though still there are many advocates of the latter) may be summarized as follows: (1) it is painless, (2) local reactions are minimized, (3) slow and uniform absorption takes place and so less toxic by-effects are produced, and (4)—a doubtful point—but I have always noted that after oily injections the patients get fat.

After injection the gold is slowly and partly eliminated, mostly through the kidney and the other part is fixed in various organs of the body from which depôts also it is slowly eliminated.

With the increase in the dosage, the percentage of elimination is also increased from 15 to even 50 per cent. Most of the elimination occurs during the first two days.

A detailed study of the distribution of gold in the body after Aurocantan administration has been made by deWitt, Cadwell and Leavell in guinea-pigs and the readings will be found of interest.

phosphorus, and iron, were investigated (Chakravorty, Mookerjee and Guha, 1933; Ghosh, Chakravorty and Guha, 1933; Ghosh and Guha, 1933; Ghosh and Guha, 1934; Ghosh and Guha, 1935; Guha, 1934; Guha and Chakravorty, 1933). These investigations revealed certain deficiencies of Indian diets in protein, in certain vitamins and in calcium and phosphorus. A study of certain cooked diets obtained from middle-class students' hostels in Calcutta (Pal and Guha, 1937) showed, however, that while there may be an appreciable deficiency in calcium, the consumption of iron seemed to be more than optimum. It was suspected, however, that most of the iron was present in an assimilable condition and was not therefore significant from the nutritional point of view. Within recent years the distinction between ionisable (assimilable) iron and total iron in food-stuffs has received special attention and investigations in this line have been carried out in numerous laboratories. The planning of a dietary should obviously be based on the supply of the ionisable iron and not merely on the basis of the total iron content. For this purpose information is necessary about (1) the ionisable iron content of individual food-stuffs and (2) the ionisable iron content of the diets, as actually consumed. The ionisable iron content of Indian food-stuffs has

changes in nutritional value during the process of cooking. We, therefore, undertook a systematic nutritional investigation of cooked dietaries in varied aspects, and in this paper the ionisable and total iron contents of some of the cooked dietaries consumed in eight students' hostels in Calcutta have been reported.

Methods.—The ionisable iron was estimated by R. Hill's aa'-dipyridyl method (Hill, 1930; Shackleton and McCance, 1936) and the total iron by the method previously described (Pal and Guha, 1937). To test the accuracy of the dipyridyl method for such materials, known amounts of iron were added to the biological material in a few cases and it was found that these could be estimated with a fair degree of accuracy, results being usually correct within 96 to 100 per cent.

Figures for the ionisable and total iron content of 16 raw plant food-stuffs are given in table I. In table II the ionisable iron (I.I.) and total iron (T.I.) contents of the cooked diets consumed by an average adult on eight consecutive days in each of eight students' hostels in Calcutta are shown. In this work an aliquot of the total mixed diet was analysed as was done in earlier work (Guha, 1934). These diets were investigated in the months of September, October, November and December 1937.

Ionisable and total iron content of 16 raw plant food-stuffs

TABLE I

Bengali name	English name	Scientific name	Ionisable iron (in mg.) per 100 g. of fresh food-stuff	Total iron (in mg.) per 100 g. of fresh food-stuff
1. Uchchhe	Bitter gourd (small)	<i>Momordica muricata</i>	0.32	3.25
2. Gajar	Carrot	<i>Daucus carota</i>	0.16	5.11
3. Aloo	Potato	<i>Solanum tuberosum</i>	1.15	1.16
4. Mula	Radish	<i>Raphanus sativus</i>	0.21	1.66
5. Patal	Patal	<i>Trichosanthes dioica</i>	0.15	1.34
6. Karala	Bitter gourd (large)	<i>Momordica muricata</i>	0.19	1.28
7. Jhinge	Sponge gourd	<i>Luffa acutangula</i>	0.08	0.77
8. Mocha	Plantain flower	<i>Spille of Musa sapientum</i>	0.18	1.41
9. Fulkopi	Cauliflower	<i>Brassica oleracea</i> , var. <i>Botrytis</i>	0.50	0.90
10. Barbati	String bean	<i>Vigna catjang</i>	0.25	1.00
11. Pepe	Papaw	<i>Carica papaya</i>	1.20	1.25
12. Chhim	Bengali bean	<i>Dolichos lablab</i>	0.25	1.55
13. Shalgom	Turnip	<i>Brassica campestris</i>	0.13	0.95
14. Mishti-kumro	Sweet gourd	<i>Cucurbita maxima</i>	0.50	1.15
15. Chal-kumro	White gourd	<i>Benincasacriapora</i>	0.25	0.50
16. French bean	French bean	<i>Phaseolus vulgaris</i>	0.45	1.22

been estimated in several laboratories in India and, in view of the differences which even the same vegetable exhibits depending perhaps on variety, soil and season, it seems desirable to have as many data as possible even on the same food-stuff in different laboratories. We have reported some results obtained with individual raw food-stuffs in this paper. But nutritional investigations with cooked diets are relatively scarce both in this and other countries, though they seem to be very desirable considering the raw food-stuffs suffer considerable

A statistical note on the significance of these figures is given by Mr. K. C. Basak.

For this statistical analysis the values for the ionisable iron content are considered. The grand mean for all the hostels and for all the days works out as 7.14 mg. of ionisable iron per head per day. It is necessary to test if the means obtained for different hostels differ significantly from the grand mean. The results obtained by analysing the above data (table II) by Fisher's (1936) method of analysis of variance are given in table III.

TABLE II
Ionisable iron (I.I.) and total iron (T.I.) consumption in mg. per head, per day

Day	Hostel 1		Hostel 2		Hostel 3		Hostel 4		Hostel 5		Hostel 6		Hostel 7		Hostel 8	
	I.I.	T.I.	I.I.	T.I.	I.I.	T.I.	I.I.	T.I.	I.I.	T.I.	I.I.	T.I.	I.I.	T.I.	I.I.	T.I.
1	7.18	31.0	8.65	35.0	6.79	36.5	3.72	31.0	6.08	31.0	9.92	43.0	9.01	47.0	6.08	34.0
2	8.27	37.2	8.28	31.0	7.62	36.0	9.12	31.3	9.47	38.0	7.72	38.5	8.00	37.6	9.14	39.0
3	7.33	39.0	8.67	39.5	8.17	43.0	8.1	42.5	8.25	36.0	8.71	37.0	10.33	41.5	7.29	39.0
4	3.61	31.0	6.63	37.8	6.17	37.5	6.91	32.0	5.9	37.2	6.08	39.5	9.14	39.0	6.54	39.3
5	6.06	33.0	6.55	37.0	1.81	31.0	5.37	30.0	5.77	31.0	5.6	36.0	6.14	38.0	6.01	36.8
6	6.91	37.0	8.91	38.0	6.31	32.0	8.78	36.0	5.61	31.5	7.19	40.0	8.32	40.0	7.65	40.0
7	7.17	39.5	6.16	33.6	5.96	37.0	6.88	33.0	8.17	38.0	7.58	39.5	6.74	38.0	6.0	33.0
8	6.21	38.5	7.5	32.0	6.02	37.0	6.62	38.5	6.42	34.0	7.62	32.0	6.12	37.0	5.96	39.0
Average	6.59	36.12	7.80	36.2	6.56	36.2	6.97	31.6	6.96	34.9	7.51	38.1	7.97	39.7	6.83	37.5
PERCENTAGE OF IONISABLE IRON	18.2		21.5		18.1		20.1		19.9		19.7		20.0		18.2	

Thus, the mean ionisable iron content of the daily diet per head for all the hostels and all the days = 7.14 mg

TABLE III
Showing the result of analysis of variance

Source of variation	Degrees of freedom	Sum of squares	Mean square	Ratio
Between hostels	7	15.8075	2.2582	1.193
Within "	56	105.9989	1.8928	..
Total	63	121.8064	1.9334	..

The ratio is not significant according to the table of Snedecor (1934).

Hence the mean ionisable iron content of the daily diets does not appear to vary significantly from hostel to hostel.

We can assume that the amount of ionisable iron is distributed normally with

$$\begin{aligned}\text{mean} &= 7.14 \\ \text{variance} &= 1.9334 \\ \text{standard dev.} &= 1.3904\end{aligned}$$

Then for a period of eight days the mean should lie in nearly 95 per cent cases

$$\text{between } 7.14 \pm 2 \times 1.3904 / \sqrt{8} (= 0.9742) \\ \text{i.e., between 8.11 and 6.17.}$$

It will be noticed that all the observed means lie within this range.

Discussion and summary

The figures for the ionisable iron content of the plant food-stuffs show that although most of them are fairly good sources of total iron, the ionisable (assimilable) iron content is only a small fraction of the total iron in all cases, except the potato of which the ionisable and total iron contents are comparable. Among the others, although the total iron content of carrot

is quite high, its ionisable iron content is less than 1/30th of its total iron, which affords an example of the great disproportion between total and available iron in many food-stuffs. Among the vegetables studied the potato seems to be a particularly good source of ionisable iron and then come *uchchhe* (*Momordica muricata*) and radish in order of quality.

The investigation of the cooked diets consumed in eight adult students' hostels in Calcutta indicate that the average consumption of ionisable iron per day per head is in the region of 7 mg. Statistical analysis of the data shows that this value is significant, as the variations from hostel to hostel are not great. Considering that the optimum ionisable iron intake is usually put down as 10 mg. or above, it would appear that there is an appreciable deficiency in the ionisable iron intake in the average students' hostel in Calcutta. It would seem, therefore, that these diets should be re-inforced by a greater proportion of food-stuffs, which contain a relatively larger amount of ionisable iron, as determined in this and other laboratories. Several variations in the diet should, of course, be considered in this connection and studies of the diets in different seasons are now in progress, so as to get a representative idea of the diet throughout the year.

Our best thanks are due to the Students' Welfare Committee of Calcutta University, without whose financial assistance this work would not have been carried out. Our thanks are also due to Dr. A. N. Chatterjee, Secretary of the Committee, who has helped us in every way in carrying out this work. The superintendents of the hostels have kindly co-operated with us by supplying diets regularly for this investigation.

THE ovary and the testis have the same mesenchymal origin and hence any remnants of the embryological rests of testicular structure in the ovary might proliferate and produce a neoplasm which might cause biological disturbances.

In the case of arrhenoblastoma of the ovary, we have a typical example of the above concept, where potential testicular cells present in the rete ovarii are developed, and through their hormone effects counter-balance the feminine characteristics, and produce male manifestations in a female.

The first description of this type of ovarian neoplasm was given by Pick (1905) who observed testicular seminiferous tubular structure in an ovarian tumour and gave the tumour the name of 'adenoma testiculare ovarii'. Meyer (1930) pointed out the probable histogenesis of this type of tumour and put forth the explanation of the sexual disturbances that are associated with this type of tumour. Novak and Long (1933), Novak and Gray (1936), and Schiller (1936), while discussing the nature of ovarian tumours, gave historical, clinical and histological descriptions of arrhenoblastoma which still remains as one of the uncommon variety of ovarian tumours. In view of the rarity of these we are describing a case which came under our observation recently.

Mrs. A. C. M., Hindu, aged 18 years, wife of an educated man, was admitted into the hospital on 20th October, 1937, with the complaints that she had had no issue, and stoppage of her periods for twenty-two months.

History.—Menstruation started at the age of fourteen; the flow was excessive, lasting for eight days on the average. At the age of fifteen she was married, i.e., three years prior to her admission into the hospital. She was having the usual marital relationship with the husband. In January 1936, six months after her marriage, the menstrual flow stopped abruptly. Three months after the cessation of menstruation, she was examined by a doctor who gave the opinion that she was pregnant; the pregnancy, however, never materialized. Towards the end of 1936, she noticed that her voice was gradually becoming heavier and husky; her friends and relations also marked this change in her voice. For this change of the voice, which was attributed to the throat trouble, various treatments were tried but were of no avail. At this period she noticed growth of hair on her face, chest, abdominal wall and the legs which increased progressively. After this, she developed a dislike for the sexual act and she observed that the clitoris was getting bigger. From February 1937, she had noticed an abdominal tumour.

On examination.—A masculine type of healthy looking young girl; weight 118 pounds and measuring 5 feet 3 inches in height. Her scalp was covered with thick black coarse short hair. There was a conspicuous male type of distribution of hair over the face, neck, abdominal wall and pubis. The voice was husky and deep and the skin was dry. The breasts were very small and flat with prominent nipples. An abdominal tumour was felt growing from the pelvis reaching up to the level of the umbilicus, occupying the left lumbar, iliac and the left half of the hypogastric regions. The tumour was fairly mobile, felt hard and not tender; no evidence of any fluid in the peritoneal cavity.

The pelvis was small, the clitoris was hypertrophied, the prepuce being very prominent and like the circumcised penis of an eight-year-old boy. The vaginal canal and the uterus were normal; the tumour mass was felt to arise from the left side of the pelvis. The heart, lungs and other organs appeared normal. Blood pressure—105/65, urine was free. The blood picture showed an average normal count. The Wassermann reaction was negative. A skiagraph of the skull showed a normal sella turcica. A pre-operative diagnosis of left-sided cyst of the ovary or an arrhenoblastoma was made. She was operated on on 1st November. The tumour was found to be a left ovarian one, about the size of a no. 3 football, irregularly shaped. The mass was solid with a few softer areas on the surface. No area of degeneration was seen. The right ovary was small and smooth. Tubes and the uterus appeared normal. The patient made an uneventful recovery and was discharged from the hospital on the 12th November, 1938. The tumour, on histological examination, showed the following interesting picture:—

There were two distinct types of structural pattern, in one of which the tubular element with definite alveolar arrangement could be seen (plate XI, figure 1), whereas in others an atypical diffuse sarcoma-like appearance was quite apparent (plate XI, figure 2). Figure 3 shows both these two different types in one area. The intracellular substance was very loosely arranged within which definite gaps could frequently be found (plate XI, figure 2). Blood spaces, large and small, enclosed by indefinite ill-formed endothelial lining, were another conspicuous feature (plate XI, figure 4). The microscopical appearance was typically of an arrhenoblastoma.

After history.—The patient was examined on the 5th January, 1939, and the following were noted:—

She started her periods twenty-eight days after the operation; her voice became much softer and distinctly more feminine. Her breasts appeared normal with regard to the size and shape and had the usual soft feeling. The clitoris was still prominent but perceptibly

Objective—10 (Leitz).

much smaller than before. The masculine distribution of the hair had disappeared and the hair was found to be just as the ordinary female type over the pubis and in the axillae; the uterus was normal and menstruation occurred regularly every month but was accompanied by pain. Marital relationship was normal except there was a certain amount of pain accompanying the act. The patient was very anxious to become pregnant.

Comments

(1) *Clinical*.—From the marked biologic disturbances that this case presented, it is evident that this was one of those described as the extreme cases, i.e., both the defeminization and masculinization were conspicuous. Most of the masculine manifestations had disappeared and feminine characters were restored after the removal of the tumour, which is usual according to all the reported cases. Schiller (1936) pointed out that restoration of female type of voice was not observed because the laryngeal change cannot retrogress; in our case she distinctly improved so far as her masculine voice was concerned.

(2) *Histology*.—According to Meyer's contention, which seems to have the widest acceptance, a great deal of correlation exists between the histological picture of the tumour and the biologic disturbances. The tubular adenomatous type producing least whereas the atypical sarcoma-like tumours are responsible for the most marked changes. By studying a number of sections of the present case we find that different portions of the tumour were composed of different types of cellular pattern, as seen in plate XI, figures 1 and 2, but the portions showing typical tubular structures are not negligible, as would be expected from the pronounced biological disturbances that this case presented, a considerable amount of tubular structure being present throughout the tumour mass.

Conclusions

(1) A case of arrhenoblastoma is recorded.

(2) The clinical manifestations and the histological structure are discussed and the association of tubular structural pattern with the marked biologic disturbances are noted.

Our thanks are due to Dr. K. G. Banerjee, M.B., Suri, Bengal, through whom the case came under our observation, for helping us in following up the patient after her discharge from hospital.

A SIMPLE MEANS OF PREVENTING SPIDER-LICK

By C. STRICKLAND, M.A., M.D.

Professor of Medical Entomology

and

D. N. ROY, M.D., D.T.M.

Assistant Professor of Medical Entomology, School of Tropical Medicine, Calcutta

IN some correspondence on the subject of 'spider-lick', Messrs. James Finlay & Co., Ltd., of Calcutta communicated to us the following passage from a letter that they had received from Mr. Jacobs, the factory manager at Riga Sugar Factory, near Muzaffarpur, in which he suggested that 'the liquid ejected by the insect . . . is soluble in water and may be washed off within an hour or two . . . and this removes its action'.

We gladly took the opportunity represented by a large collection of the insects that were forwarded from the same source to try out the hypothesis.

A powerful tincture prepared from the specimens and matured since May 1938 was used for the experiments on two volunteers. In each experiment approximately equal quantities of the fluid were used for it and for the control.

Experiment I.—In the first experiment both forearms of volunteer A were painted with the tincture. One hour afterwards the left forearm was washed in tap water. Two days after the right arm showed a marked dermatitis, while the left arm had a few rosary papules only.

Experiment II.—The left and right forearms of volunteer B were painted with the tincture by means of a camel-hair brush. His name was written with the paint and after his name a cross. One hour after the tincture had dried the left forearm was washed in running tap water, soap not being used.

The next day he noticed a slight reaction on the right forearm only.

The following day this had developed into a severe dermatitis showing confluent vesicles. On the other hand the left forearm showed a few isolated papules only.

Subsequently the left arm showed no more reaction than that.

Experiment III on volunteer A.—As the undiluted tincture had shown itself very severe in its reaction when the dermatitis was fully developed, the fluid was in this experiment diluted with 9 parts of rectified spirit before use. Washing the arm was done 2 hours afterward. The unwashed area developed a mild dermatitis, the papules being scattered, and the washed arm showed no reaction.

These few controlled observations thus confirm the observations made by Mr. Jacobs and indicate that attention to regularly bathing the parts that are not commonly covered with clothes should suffice to prevent the condition

arising. As the insects are nocturnal in habit, being, in their relation with man, strongly attracted by lights, it is essential that the sug-

gested attention to washing should be unrelaxed after dark, however little be given to it during daytime.

A Mirror of Hospital Practice

A CASE OF CEREBELLAR APOPLEXY

By F. R. W. K. ALLEN, M.A., D.M., M.A.O. (Dublin Univ.), M.C.O.G.

Superintendent, Robertson Medical School, Nagpur

G. L. SHARMA, D.M.

Lecturer in Pathology

and

I. B. BASU

Surgical Registrar, Mayo Hospital, Nagpur

THE following case of thrombosis in the posterior inferior cerebellar artery seems interesting enough to be placed on record:—

C., aged 35 years, Hindu male, was admitted into the hospital on the 10th August, 1938, with the following complaints:—

1. Inability to walk.
2. Difficulty in swallowing food and drink.
3. Difficulty in speaking clearly.
4. Dizziness.
5. Vomiting.

Family history:—Nothing important.

Personal history:—Addicted to alcohol and heavy smoking.

Past illness:—Contracted syphilis about 15 years back. Two years back he was admitted to this hospital for pain in the præcordium (angina pectoris?).

Present illness:—The patient drank country liquor in large quantities on the 7th August, 1938. He slept well in the night but the following morning he vomited a few times and was markedly dizzy. As there was a cholera epidemic in the city, he thought he was suffering from cholera and sent for a doctor, who prescribed him some mixture. The patient took two doses of this, but could not swallow the third dose which regurgitated. Soon after, he noticed that he could not stand. He fell down on his left side. The left upper and lower extremities appeared to be weaker than the right ones. His speech became thick.

General examination:—The patient looks strong and well built. His left eye looks smaller than the right. On standing his dizziness is increased and he loses balance.

Examination of nervous system:—Intellectual functions—Nothing abnormal.

Cranial nerves:—(1) Trigeminal nerve—There is analgesia and thermanæsthesia on the left of the face.

(2) Glossopharyngeal, vagus and accessory nerves—There is paralysis of the soft palate on the left side, and dysarthria. There is difficulty in deglutition.

Oculo-pupillary centre:—There is miosis and enophthalmos on the left side.

Motor functions:—Analgesia and thermanæsthesia on the right half of the trunk, right upper and lower limbs and left half of the face.

Reflexes:—Absent on the left side.

Plantar reflex:—Flexor on both sides.

Organic reflexes and sphincters:—Nothing abnormal.

Cardiovascular, respiratory and alimentary systems:—

Nothing abnormal detected. His blood pressure on the day of admission was 155/100 mm. of mercury.

Fundus oculi:—Normal.

Fluoroscopic examination of the heart and blood vessels:—Nothing abnormal found.

Laboratory findings:—Urine—Nothing abnormal.

Blood:—Wassermann reaction—Strongly positive.

Cerebro-spinal fluid colloidal gold test:—Luetic curve.

Treatment:—As he could not swallow any solids or fluids he was fed with milk poured down the stomach tube. Eutodon 2 c.cm. was given intramuscularly daily for 20 days. This was followed by tryparsamide intravenously, first dose being 0.1 gramme, and subsequent nine weekly doses of 0.3 gramme each. Casbis 1 c.cm. was administered intramuscularly thrice a week on 20 occasions.

He can now eat and drink normally. He walks about and does his business as a hair-oil manufacturer. His speech is clear. He has no dizziness. His blood pressure is 140/98 m.m. mercury.

AMELIA

By D. R. VAIDYA, M.B., B.S. (Madras)

Obstetric Registrar, Sassoon Hospital, Poona

THIS congenital deformity is very rare.

A woman, aged 32, was admitted into the maternity section of the Sassoon Hospital.

Obstetrical history:—4th para. All deliveries were normal.

On 16th February, 1938, she was delivered normally of a male child weighing seven pounds. The baby had no upper extremities; there is no other congenital mal-development and the child is thriving well.

An attempt was made by taking a skiagram to note whether there were any rudimentary arm bones. It shows no evidence of extremities and clavicles and scapulae are normally developed.

It was suggested that this may be a case of intra-uterine amputation but the absence of scars, or any sign of upper extremities dismisses this possibility.

There is no history of hereditary deformities in the families of the parents and grandparents.

Volume I, the *Practitioner's Library of Medicine and Surgery*, 1932, mentions this condition under the name of 'Amelia'. Another book which has described the condition is the *Encyclopædia of Medicine* under the name 'Abachia'.

Patient was discharged on 21st February, 1938.

My thanks are due to Lieut.-Col. R. H. Candy and Lieut.-Col. F. R. Thornton for allowing me to publish the case.

[Note.—Amelia strictly means the absence of all limbs so abrachia would be more correct, but the *British Encyclopædia of Medical Practice* uses ectromelia for absence of one or more limbs.—EDITOR, I. M. G.]

POSTERIOR BASAL MENINGITIS IN A CHILD

By D. A. GANGOLLI, L.C.P.S.

Medical Officer, In charge Dispensary, Bhayndar
(District, Thana)

A MALE child about a year and quarter old was brought to the dispensary on the morning of 4th July, 1938, for the treatment of high fever with unconsciousness for the last six days.

Previous history.—The child had been quite normal and healthy since its birth and on the evening of 28th June, 1938, it suddenly got high fever with vomiting, convulsions and epistaxis. Consciousness was soon lost and the child ceased feeding.

Condition on admission.—Temperature 104.2°F. Pulse 136 per minute, feeble and irregular. Child in an unconscious condition. Head markedly retracted

with stiff neck. Internal deviation of both the eyeballs, and the eyes widely open and staring. No photophobia. Both the upper and lower extremities spastic. Heart and lungs normal. Spleen and liver not palpable. No tuberculous focus could be detected anywhere in the body either in the lungs, glands or bones.

Treatment.—Lumbar puncture was decided upon but was refused by the parents, so only medicinal treatment was resorted to. Calomel grs ii was applied to the tongue mixed in honey and a diaphoretic mixture containing full doses of urotropine was given. Temperature came down to normal the same evening with profuse diaphoresis, and on the next morning consciousness was regained. For the next three days the diurnal range of temperature varied between 98°F. in the morning to 101.4°F. in the evening, after which it remained within normal limits. Convalescence now set in and the squint in the left eye gradually passed off while that in the right eye did not show any progress towards recovery. The stiffness in the upper limbs passed off while that in the lower limbs remained for a longer time. The child often-times lay on its back for hours together absolutely motionless without making the slightest attempt to move its lower limbs and it shrieked violently whenever an attempt was made to move them forcibly. Massage combined with passive movements together with hot baths gradually restored the power in both the lower extremities and the child appeared quite recovered. At this stage the treatment was abruptly terminated and nothing more of the child was heard till 28th December, 1938, when it was again brought into the dispensary. On inspection it was found that the child was perfectly normal except for the squint in the right eye which still persists and this defect, it seems, will remain permanently. The child keeps its face turned towards the right side and a peculiar form of torticollis is present. Diplopia is present as when an object like a lead pencil is held on the child's extreme right it tries to catch at an imaginary object away from the pencil while on the left side no such difficulty is experienced.

Comments.—A sporadic case of posterior basal meningitis in a child diagnosed clinically is described. This case is interesting on account of the following facts:—

1. The child recovered though no lumbar puncture was performed.

2. The child escaped from the most common complications of this disease which are described in the ordinary textbooks such as hydrocephalus, mental impairment and deafness, while it suffered from a most unusual complication of paralytic squint and diplopia in the right eye due to paralysis of the sixth cranial nerve and consequently of the lateral rectus muscle of the right eyeball. The abducent nerves are liable to be affected on one or both the sides simply by increased intra-cranial pressure, as in acute meningitis, due to the long course of the nerves in the cranial cavity, giving rise to squint in the eyes as seen in the case of the present child in the early stages. But when the acute stage passes off the pressure on the nerve trunks is relieved and the eyes recover. In the present case, it seems that in addition to the pressure on both the nerves there was an exudation of fibrinous material along the course of the nerve on the right side which not being completely absorbed was converted into fibro-cicatricial tissue causing permanent adhesions of the nerve trunk, leading to deformity and defective vision in the right eye.

ON A FOREIGN BODY INTRODUCED BY GUNSHOT

By K. B. CHAKERVERTY

Medical Officer, Ambootia Hospital, near Kursong

THE following account of a foreign body introduced by gunshot and lying quiescent in the tissues for 17 years may be of some general interest :—

A Nepali ex-sepoy, now aged 42, had a gunshot wound in the buttock in 1921, when he was on duty in the Moplah rebellion in Malabar.

The bullet was removed at the time, the wound gradually healed and after three months the patient was discharged as cured.

He subsequently retired from the service and came to Ambootia tea estate with other members of his family. From 1923 onwards he has worked on the tea garden without anything untoward except for slight discomfort when lying down on the old site of the wound, and occasionally pain after a long journey. Since 1925 he has worked as dispensary compounder.

On the 21st December, 1938, he suddenly developed acute inflammation with severe pain at the site of the wound, and fever which continued for about a week. The treatment given was the continuous application of a hot borie compress. The part soon suppurated

and made a point outward with a hard sharp edge which I suspected to be a necrosed bone. An incision was made to open the cavity and firmly holding the foreign body with forceps it was pulled out.

On examination it was found to be a broken piece of iron weighing about 148 grains (*see* photograph made against a 2-anna piece). The patient is now completely well and free from all the troubles that he so long experienced.

A *khookri* was hanging at his waist at the time of his gunshot wound, and it appears that a broken piece of the *khookri* gained entrance into the tissues with the bullet and, when the bullet was removed, the broken piece of the *khookri* was left behind unnoticed.

It is interesting that the patient should have carried on his work with such a comparatively large piece of iron in the tissues, and that it was

possible for it to remain there for so long (17 years) without any serious ill effects.

ERYSIPELAS IN A CHILD AGED 6 DAYS TREATED SUCCESSFULLY WITH PRONTOSIL RUBRUM (BAYER)

By SUDHIR CHANDRA ROY, B.Sc., M.B., D.T.M.

Kurigram, Rungpur

A FEMALE child, aged 6 days, was seen on the third day of her illness. She had erysipelas extending from the chin to the middle of right scapula on the back and nipple on the front of right side of chest. The child was very restless and her temperature was 106°F. The patch at first began on the back of the neck and spread rapidly.

Prontosil rubrum was given as:—

R Prontosil rubrum 1 tablet
Saccharum lactis gr. 20

Fiat. pulv.; divide it into 12 powders. Sig. one powder to be taken every 4 hours (four times daily).

Ichthyol, 30 per cent aqueous solution, was applied locally.

Next day the temperature came down to 102°F, and the spreading margin was arrested. On the sixth day of the disease the temperature came down to normal, but as the redness of skin was still present another tablet of prontosil was given as before. The child then recovered uneventfully.

Remarks

I am sending this report because it is interesting that such a young child was given prontosil successfully without showing untoward symptoms.

A RARE CAUSE OF SUDDEN DEATH

By D. P. LAMBERT, M.B., D.T.M. & H.

MAJOR, I.M.S.

Civil Surgeon, Meerut

EARLY in the morning on 12th January, 1939, a man of 65 uttered a cry and collapsed. Before any help could be brought he died. At post-mortem examination, eight hours later, both suprarenal glands were found enlarged, particularly in relation to the man's stature and physique, and there was a large recent hæmorrhage into the right suprarenal gland. The suprarenal arteries were tortuous and slightly thickened. There was similar tortuosity and slight thickening of the cerebral arteries and of the coronary arteries. The great vessels and the other peripheral arteries were normal. The left ventricle was hypertrophied, but the myocardium was healthy, and no other abnormality was present in the heart. There was moderate enlargement of the spleen probably malarial in origin. The liver showed early 'nutmeg' congestion, and there was a solitary pigment stone in the gall-bladder. The lungs showed fairly extensive healed tuberculosis at the apices, especially on the right side. All the other viscera, and in particular the kidneys, were normal.

Hæmorrhage into a suprarenal gland is one of the rare causes of sudden death. There is no ante-mortem record of this man's blood pressure, but it is almost certain that it was high. It is tempting to relate this to the hypertrophy of the suprarenal glands and to speculate whether Leriche's operation of unilateral supra-renalectomy might not have prolonged the man's life.

I am indebted to the Inspector-General of Civil Hospitals, United Provinces, for permission to publish this note.

Indian Medical Gazette

MAY

CHEMOTHERAPY IN PNEUMONIA

In our October issue of last year, whilst discussing the treatment of lobar pneumonia, we referred to the recent experimental work of Whitty who had selected a drug, 2-sulphanilyl-amino-pyridine, as being the most active drug so far tested in protecting mice against pneumococcal infections; we added that this drug had been used clinically with very promising results, and concluded with the following paragraph:— 'It is too soon to be jubilant about this particular compound, but we are certainly entitled to be optimistic regarding the future of chemotherapy in this disease. The very great advantage of the drugs of this group is that they are not expensive and it seems possible that herein lies the solution to the problem of the treatment of lobar pneumonia in this country'.

At the time this was written the only paper on the clinical use of this drug that had reached us was Evans and Gaisford's very convincing series of one hundred cases treated by 'M. & B. 693' (2-sulphanilyl-amino-pyridine) with 100 controls treated by the 'usual routine non-specific methods'. The results of this first important clinical trial were very striking; the death rate in the treated series was 8 per cent and in the controls 27 per cent, a very significant difference.

This first clinical report was soon followed by those of other workers in Great Britain who obtained equally good results, and this year a number of reports have been received from the colonies.

Anderson and Dowdeswell from Nairobi reported a trial in 50 cases with 50 controls: in the cases in which M. & B. 693 was used there was only one death and in the control series there were 8 deaths. From Johannesburg a very extensive series, consisting of over five hundred cases and controls, is reported: there were 10 deaths in a series of 266 cases treated by M. & B. 693 and 27 deaths in the control series of 257, death rates of 3.8 and 10.5 per cent.

In the Nairobi series the difference is not quite significant statistically, but in the Johannesburg series it is very significant, and if the latter series is analysed it is seen that the improvement in mortality figures is more marked in certain sections of the community, for example, in the Johannesburg hospital patients who are taken from the general community and include a higher proportion of old people. Another difference is that the labourers in the

mines are strong and healthy individuals who are under constant medical supervision and have been inoculated as a prophylactic measure; in this class the normal mortality rate is low and the improvement is not so marked.

The reduction in the death rate is the final criterion of the value of every drug, but from the practitioner's point of view the immediate effect on the symptoms of the disease is often of considerable importance, and M. & B. 693 is remarkable in its immediate effect, not only on the symptoms but on the pathological processes; it brings about a very rapid fall of temperature within 24 hours in a majority of cases and appears to stop the extension of consolidation.

In the Nairobi series the temperature fell to normal within 24 hours in 26 cases (52 per cent), within 48 hours in 44 cases and in every case within three days of the institution of specific treatment with M. & B. 693.

It is as yet too early for any final decision as to the optimum dosage to be arrived at, but the tendency at present is towards a slightly larger dosage than was at first used. Evans and Gaisford at first gave one tablet (0.5 gramme) every 4 hours but later increased this to two tablets (1 gramme). The procedure that is usually adopted now is to give an initial dose of 2 grammes and follow this by 1 gramme every four hours for the first 3 or 4 days, and then to give 1 gramme twice a day for a few more days. Too early discontinuance of treatment may lead to the extension of the pathological process to another lobe during the second week. The total dosage may thus amount to 36 grammes, but this is seldom necessary and the average total dose in the cases so far reported is not more than 25 grammes. In the Nairobi series the average was 18.5 grammes and in the various Johannesburg groups it was 31, 29, 24 and 14 grammes.

The ill effects of this therapy in certain cases are much the same as, though possibly less in frequency and seriousness than, those associated with other sulphanilamide preparations, and, in the treatment of a serious condition such as this, the slight risk fades to negligible proportions. However, the same precautions regarding the taking of sulphur-containing drugs and foods must be observed.

Elsewhere in this number will be found a paper reporting the results of the treatment of pneumonia by M. & B. 693 at Lahore.

The same very promising results have been obtained; in a series of 50 treated cases and 50 controls the death rates were 10 and 18 per cent respectively, but again the most striking effect of the treatment was the extremely rapid fall of temperature, in 39 cases out of 50 the temperature falling to normal within 48 hours. We have also received information regarding its use in an industrial community in India, where over a certain period last year the death rate amongst

the pneumonia cases was as high as 60 per cent: in a corresponding period this year only 3 deaths have occurred in a series of 48 cases.

In our previous editorial we mentioned that the drug was not expensive. Expense is necessarily a comparative term and at that time we were comparing the cost with that of the serum treatment of pneumonia. The high cost of serum treatment of pneumonia prohibited its extensive use in India and as serum is a biological product it is impossible to reduce its cost to

any important extent; but this does not apply in the case of synthetic preparations of the sulphanilamide group. Even at the present day the cost of the treatment of a single case is not high considering that it doubles the patient's chances of recovery. The time may not be far hence when this or some equally efficacious drug will be available at a price within the reach of India's masses, and the prophecy contained in the last sentence of our October editorial may be fulfilled sooner than we dared to hope.

PUBLIC HEALTH—THE FOUNDATION OF NATION BUILDING

(BROADCAST TALK by SIR A. H. RUSSELL, C.B.E., K.H.S., COLONEL, I.M.S., *Public Health Commissioner with the Government of India*)

MANY of you no doubt are acquainted with the Biblical story of the wise man who built his house upon a rock in contradistinction to the foolish one who built upon sand with disastrous results. Similarly in nation building, we must be sure of our foundations and it is my purpose to-night to try to demonstrate to my listeners that the one sure foundation on which to build a happy and prosperous nation is that of health, not only health of the individual but health of the community. We are all so apt to leave community health, or public health as it is usually called, to the other fellow, forgetting that it is the cumulative effort which counts so much. So it is that I have no hesitation in claiming that public health, and all that that phrase implies, is the sure foundation on which to erect the structure of national wealth. Without that foundation, no nation can hope to be strong enough to resist successfully the strain of economic and social storms.

The purpose of all nation-building activities is to make the life of every citizen fuller, richer and happier. This implies that the individual citizen should be provided with suitable opportunities for desirable self-expression, in respect of his physical, intellectual and emotional equipment, because only by that means can he hope to enlarge his experience and his capacity for enjoyment of life. Modern public health development stands for the creation and maintenance of all those conditions which will enable each individual to attain these objects. Sickness, pain and suffering, poverty, malnutrition, maladjustments in his home or in his work or in his social environment, these are largely responsible for depriving the average citizen of his inherent right to enjoy life. A well-organized public health campaign must take cognizance of all those deterrents to happiness and I for one believe that in the advance of public health we have the solution.

For many centuries past, human society has recognized the necessity for treatment and care of the sick, but the conception of prevention of disease and sickness by means of an active programme of ameliorative measures intended to render it possible for the people either to maintain health, or, at least, to live more healthy lives, is one of much more recent origin. In fact, it is not yet 100 years since in England the importance of preventive medicine came to be recognized and was made the foundation of the many-sided social and health services now in existence in that country.

But, you may ask, how does the public health worker seek to bring greater happiness to the individual and

to the community? It is by no means easy to summarize in a brief talk the many different directions in which health work should be planned, because it has become obvious—at least to those who have real vision—that preventive medicine includes in its range of activity 'the whole nature of man, as shaped by his home, his surroundings, his work, his recreation, his struggles and his aspirations'. This, as you will appreciate, is a formidable task, but, for my purpose to-night, it might perhaps be divided into four parts:—

(1) State-aided health services capable of providing care for every individual, from the pregnant woman and unborn child to the adult and the aged. These services would also include separate branches for special health problems, such as those associated with tuberculosis and leprosy.

(2) Improvement of environment by the provision of sanitary houses, fresh air, pure water and nourishing food, both for humans and cattle.

(3) Education of the people—especially the wives and mothers—in the principles of health so that the active co-operation of every individual may be obtained. The search for health demands the abandonment of many undesirable habits and the practice of others which science has shown to be necessary to man's well-being, but here perhaps we are faced with our greatest problem because 'all our life, so far as it has a definite form, is but a mass of habits', good, bad and indifferent and the inherent inertia of man always acts as a serious handicap to change.

(4) Promotion of physical and mental welfare with the object not only of increasing the resistance of the body to disease and of promoting happiness in bodily activities, but also of assisting the individual to secure harmonious development of his intellectual and emotional faculties.

Such a comprehensive programme must of necessity lay a heavy burden of expenditure on the State and, even in the wealthiest countries, it has been found impracticable to carry it out other than by successive stages, and, then only, as and when the necessary public funds become available. It is not sufficiently realized, however, that all social and economic progress is seriously hampered by sickness and a low level of physical fitness, and this is particularly true of India. Improvement of public health is essential if, for instance, the working capacity of the agricultural or industrial labourer is to be raised; and those acquainted with existing conditions in this country are only too well aware of the handicap to efficiency which is caused by bad health and poor physique. The fact that the deaths from malaria in British India alone total 1,250,000 yearly indicates the amount of suffering, incapacity for work and loss of income caused by this one disease, especially among the rural agricultural populations on whose productive capacity the prosperity of this country so very largely depends. Another striking illustration may be found in the large numbers of deaths among young mothers and their infants, and these, of course, represent only a small fraction

of the amount of ill health and suffering which is borne by the women of India. Whilst no estimate can be made of the economic loss these and other mortality figures represent, although it must extend to many crores of rupees each year, they certainly point to the necessity for progressive health work as the essential foundation for sound and secure nation building.

Another aspect of the economic question is that State action directed towards improvement of health has undoubtedly beneficial repercussions in many other directions. Take, for instance, the question of nutrition. During recent years, we have been able to obtain a more accurate picture of the amount of malnutrition from which the people of this country suffer, and it has also been shown that an adequate state of nutrition is of the greatest importance, not only in the prevention of disease but also in increasing man's resistance to infection and his sense of well-being. Solution of the nutritional problems in India, however, depends on improved agricultural and animal husbandry practices, the development of trade and industry, the encouragement of co-operative enterprise, banking and other activities. There is no shadow of doubt that every step towards better national health will lead to the development of all those activities which are so fundamental in any nation-building campaign.

Improvement of public health demands that every individual should develop a sense of responsibility in respect of his neighbour's welfare in addition to his own. It is not enough for the house-holder to keep his own restricted environment tidy and clean, if by doing so he creates afresh conditions favourable for the development of ill-health in his neighbour or in the community. Modern science has shown that, in matters relating to health, man is his own worst enemy and much of the disease which now works havoc over large areas could be avoided if the community sense were better developed and if the individual were brought to realize the danger of his own actions to community health.

The remedy for these errors, which are usually but not always the result of sheer ignorance, lies in health education, that is, in teaching the people how to avoid actions which assist in the spread of disease. Such instruction is essential for real citizenship, because it is only when the individual comes to realize that his interests and those of his neighbours are identical in respect of health matters that he develops the wider outlook which is so essential if his actions in other spheres of life are to be to the benefit of the State and to his fellow citizens.

The history of the public health movement in England and elsewhere clearly indicates that the initial stimulus towards necessary reform has repeatedly come from private individuals or from voluntary organizations. Whether it be in respect of factory legislation for the improvement of the conditions of factory workers, of measures for saving the lives of mothers and infants, of prevention of tuberculosis or of other efforts for alleviation of human suffering voluntary effort has led the way to State action in practically every civilized country. Even when Governments have assumed responsibility, there always remains room, however, for the resources in time, money and labour of humanitarian individuals and voluntary organizations in supplementing official activities. It has been remarked that 'to save and prolong man's life, there is nothing so effective in the long run as collective humanism'. There is no doubt that 'collective humanism' is a living force in this country, as the recent result of Her Excellency's appeal on behalf of the tuberculous sufferer has indicated, but the urge towards high human endeavour requires a much wider development if it is to meet adequately the heavy and urgent demands which must be obvious to all thinking men and women in this country. In so far as the public health movement can help to foster man's fellow feeling for man, its contribution towards nation building will be of an enduring and beneficent nature, resulting in a vastly desirable increase of human happiness and well-being.

BASIC PRINCIPLES OF SOLARIUM TREATMENT*

By P. M. MEHTA, M.D., M.S., F.C.P.S.

Director, Solarium, Jamnagar

Historical survey of ray therapy

RAY therapy means the treatment of diseases by solar radiations, as well as by those produced by artificial sources. The latter have come into being during the last few decades. The solar rays have been used by men since time immemorial. Even animals have been observed to expose their injuries to the rays of the sun. The men of the stone age selected their cave dwellings for their favourable situation for the admission of sunlight. In all ancient religions the worship of the sun finds a premier place. The Egyptians worshipped Ra which means the sun. Their kings were called Pha-ra-oh, i.e., the deputies of the Sun-God. From an ancient Egyptian picture, it appears that Egyptians took sun-baths. Heliotherapy, as such, was first practised by the Greeks. From them the practice was honoured by the Romans. They built sun houses which they called solaria. These were generally apartments made in dwelling houses for the purpose of sun-baths. Such solaria were also attached to the halls of the sick in hospitals. In India the therapeutic use of solar radiations seems to have been carried further than mere exposure in the interests of general health. There are clear references to cures of leprosy and skin diseases by exposure to the sun (*vide* Mayur's *Surya Shatak*). But we have no grounds to conclude that heliotherapy was systematically practised here. We may trace the history of ray therapy to these ancient practices, but strictly speaking they have no bearing on the subject. The present-day ray therapy cannot in any sense be said to have developed from them. The first seed of ray therapy was sown by Newton in 1666 when he discovered the spectrum. It was this discovery which later led to the discovery of invisible radiations and artificial production of rays. The seed was to begin bearing fruit two centuries later. During that period the science of light and electricity made great progress. The invisible infra-red and ultra-violet rays and the Hertzian waves were discovered. The progress in physics and science generally was a necessary condition precedent to the rise and growth of ray therapy. The knowledge of the ingredients of sunlight and the mechanical contrivances for production of radiations are the foundations on which it is based. Finsen and Rollier may be called the fathers and pioneers of ray therapy. Finsen showed that lupus was curable by ultra-violet radiation. He contributed much to the development of methods and technique. After him

*Being a paper read before the meeting of the Baroda Medical Union on the 9th August, 1938.

Rollier opened an institution in the Swiss Alps for the scientific use of heliotherapy. He had much success in the treatment of anæmia, chronic ulcers, and surgical tuberculosis, specially tuberculosis of the skin, bones, joints and glands. His extensive work following Finsen's, inspired many scientific investigations and applications of the present century. With Röntgen's discovery of x-rays in 1895 and the isolation of radium by the Curies in 1898, the present century was prepared for intense application of radiant energy in therapeutic practice.

During the last 25 years many new sources of ultra-violet, visible and infra-red rays have been developed.

Dr. Saidman of Paris designed the solarium mainly to utilize the sun's rays. The whole construction has been planned so as to make use of radiation, specially solar, in the most scientific way. He built the first solarium at Aix-les-Bains, Paris, where his late Highness Jam Sahib Ranjitsinhji happened to be treated. With his usual acuteness of observation he at once saw that the usefulness of a solarium in a sunny country like India would be much greater than in Paris where sunlight was not available so continually. He saw that the solarium if made in his State would not only be a boon to his subjects but to the whole of India, and he decided to build a solarium at Jamnagar. Unfortunately, he did not live to see it erected and working, but it stands as a permanent memorial to the greatness of that prince who always thought ahead of his times and whose work has proved to be of lasting benefit to his people and countrymen. Inspired by the same spirit, the present Jam Sahib carried to completion the construction of a solarium at Jamnagar. There are only three solaria in the world. This being the latest is the best equipped and most up to date.

Present status.—Solarium treatment means ray therapy. Ray therapy has not yet won the recognition of the universities. Without academic sanction the spread of a new system is necessarily slow. Quackery and exploitation of diseases for profit are so rampant that even a genuine and scientific innovation cannot escape the scepticism and suspicion, but sun-ray treatment is now generally accepted by the profession, whose interest in this subject is daily increasing.

Rationale.—In medicine and surgery we follow chemical and mechanical methods. These seem to be quite natural and adapted to the body whose actions are nothing but a series of chemical and mechanical processes. Ray therapy breaks new ground altogether. A dose of ultra-violet rays sounds strange, but it is as scientific as any other system of medicine. In fact it reflects in the therapeutic field the latest development in science.

Chemistry looks upon the atom as the smallest irreducible particle of an element. Physics has

carried the quest into the mystery of matter further and discovered in the atom a solar system on an unimaginable infinitesimal scale. Every atom is made up of electrons and protons. The electrons in the atom keep revolving round the protons just as the planets do round the sun. Some idea of this miniature solar system will be obtained when I tell you the size of an average atom to be one four hundred millionth of an inch, of an electron to be $3/20,000,000,000,000$ of an inch and of a proton $1/25,000,000,000,000$ of an inch. Small as the atom is it is still big enough to contain a solar system with sun and planets placed at distances from each other on the same scale as the visible solar system or even larger. The electron is capable of attaining a speed of 540,000,000 miles per hour. The mind reels at such minute sizes of particles of matter and the enormous speed at which they are capable of travelling. Each electron carries a unit charge of negative electricity and the proton carries a charge of positive electricity equal to that of the sum total of the electrons. A disturbance in this equilibrium by the addition or subtraction of electrons causes some atoms to be charged with positive electricity and others with negative electricity, and is responsible for such a phenomenon as the lightning. Any disturbance in the stable condition of the atom whether brought about by variation in the number of its electrons or in the speed with which they revolve or in their orbits causes ripples in the ether, which go on travelling in space till they are absorbed.

This is believed to be due to electro-magnetic attraction and repulsion of electrons and therefore these waves are electro-magnetic waves. The universe has become what it is on account of this play and interplay of electronic energy. So far as we are concerned and so far as is known at present life has taken shape in this world as a result of radiation, i.e., electro-magnetic waves transmitted from the sun. The quality of every cell in the organism, its growth and functions, its environment and evolution are all determined by the innumerable kinds of radiations which flow from the sun. The physiological action of these radiations which have made us what we are is therefore undoubted though we do not know it perfectly.

In days when chemistry had not developed, herbs or substances which were known to have beneficial effects were administered wholesale. Chemistry analysed them and isolated the useful ingredients and thus avoided the unnecessary waste of bodily energy involved in the process of throwing out the unwanted ingredients. In physical therapy we go a stage further, i.e., the passage from chemical methods to radiation methods marks a further stage in refinement. Instead of making a tincture we prepare a ray which has a selective action on the cells of the part to be treated. The part is directly approached. You will thus see that ray therapy is as natural and rational or even more than

chemical medicine at first sight appears to be.

The cells of the body cannot be dealt with effectively except by radiation of the particular type to which they respond. Some rays they reflect, some they allow to go through, and some they absorb. It is the task of ray therapy to know the selectivity of the bodily cells and of the radiations. The phenomenon of colour makes it obvious that there is a subtle scheme of selectivity which pervades all creation. Red objects absorb all visible rays except the red ones. Yellow things absorb all visible rays except the yellow ones. This colour selectivity is with regard to the very small segment of the spectrum known as the visible spectrum. The selectivity of the rays comprised in the vastly greater invisible segments of the spectrum is not so easy to detect but it cannot be doubted that for each kind of cell there are radiations which act on them in a particular way. It may be destructive or constructive. We have an example in the *gamma* rays of radium which from all other cells of the affected parts select the cancer cells for destruction. To explore the selectivity of radiation with reference to bodily cells is the main business of ray therapy.

Physics.—In 1666 Newton laid the foundation of ray therapy. In that year he discovered the spectrum and showed that the white sunlight was composed of seven different colours. By passing a beam of light through a prism it was broken up into its component parts. The spectroscope is the instrument employed for this purpose. Not only solar light but any light produced from any substance heated to incandescence stage can be thus broken up. By passing it through a spectroscope an image is obtained in which different colours are shown. This discovery of Newton later led, as we shall see, to the discovery of various invisible radiations which are used in ray therapy. These colours are always arranged in a fixed order. The location of these colours on the spectrum relatively to each other is never changed. Their position is determined by their wave-lengths. The shortest wave-lengths come first and then the longer and so on. This brings us to the important question, what is wave-length?

We have seen that the radiant energy is transmitted in ripples or waves. The distinctive feature of a wave as we know is alternate, dip and rise so that there are successive crests with hollows in between. The distance between two crests is the length of the wave, and is technically called wave-length. Wave-length is the one quality which differentiates one ray from another. The difference in red and yellow radiation, *i.e.*, the difference in colour effect, is due to difference in wave-length. If it is possible to change the wave-length of red radiation into that of yellow the colour effect will also change but such change is thought impossible at present. To give the wave-length of a radiation is to define it completely. We do not know why

but the difference in wave-length makes one radiation highly penetrative, another to have biological effects, another to have heating effects, and so on. Wave-lengths are measured in terms of the Angstrom units which is one ten millionth of a millimetre. The wave-lengths of the visible rays are as under :—

Violet	3,900-4,300A.
Blue and indigo	4,300-4,900A.
Green	4,900-5,500A.
Yellow	5,500-5,900A.
Orange	5,900-6,200A.
Red	6,200-7,700A.

This is also the order in which they appear in the spectrum. This portion of the solar spectrum is called the visible. This is not the whole spectrum. It is in fact an infinitesimal part of the solar spectrum. There are invisible radiations beyond both ends of the visible spectrum. The proportion of the visible spectrum to the entire electro-magnetic spectrum is thus described by Luckiesh. If the normal spectrum of this entire range of wave-length of radiant energy could be produced and the portion of it due to visible radiation in light were one foot long, the entire spectrum would be several million miles long. The invisible spectrum on the violet end is called the actinic or chemical spectrum as the rays on this side have marked chemical action. So far the following rays have been discovered on this side :—

		Used in medicine
Cosmic rays	.. 0.003-0.006A.	No.
Gamma rays	.. 0.02-1A	0.1A.
X-rays	..	
Ultra-violet rays	2,000-3,900	2,000-3,900A.

The invisible spectrum on the red end is called the thermal spectrum as the rays have marked heating action. The radiations known on this side are :—

Infra-red	.. 7,700-500,000A.	7,700-80,000
Hertzian waves	.. 500,000A to many kilometres.	3-30 metres.

Apart from the *gamma* rays of radium and Röntgen rays and cosmic rays which form separate subjects the rays mainly used in ray therapy are ultra-violet, visible, infra-red, and short Hertzian waves.

Next question is, from where do we obtain these rays? There are two sources of radiations, natural and artificial.

Sources.—The natural source is the sun. The size of this huge glowing radiator is three hundred thousand times that of the earth. All possible radiations emanate from the sun as all the 92 elements which compose matter are in the sun in incandescent condition, at a temperature of 10,000°C. Out of the total radiant energy issuing from the sun, we intercept a two thousand millionth part of it. This fraction passes through about ninety-three million miles of ether and through about a hundred miles of the earth's atmosphere. Ether is not absorbent so the radiations are absolutely unchanged till they reach the atmosphere. This atmospheric

envelope of earth absorbs about 40 per cent of these radiations allowing 60 per cent to come in contact with us. This 60 per cent is also not received uniformly at all places and at all times. The average solar spectrum extends from approximately 2,900A to 50,000A. This range covers a portion of the ultra-violet rays, the visible rays and a big slice of the infra-red region. The shorter wave-lengths below 2,900A are absorbed by the clear ozone in the upper atmosphere.

After that the local variations in the atmosphere affects their further progress towards the earth. When the sun's rays have to pass through a longer column of atmosphere, as in the morning and evening, the absorption of shorter ultra-violet rays is greater. Similarly, where there are more dust particles in the atmosphere as over big cities the ultra-violet rays are greatly absorbed. Big industrial towns have very poor ultra-violet value.

The solar spectrum is continuous, beginning from 2,900A to about 20,000A, faintly extending up to 50,000A. The percentage of various wave-lengths in the solar spectrum is :—

2,900- 4,000	3.9 per cent
4,000- 7,600	43.7 "
7,600-15,000	35.6 "
15,000-50,000	16.8 "

On clear days the maximum intensity of illumination due to direct sunlight is about 8,000 foot-candles and to combined sunlight and skylight is as great as 10,000 foot-candles and the maximum intensity of energy varies from 1.5 to 1.45 calories per square centimetre per minute. This energy is sufficient to melt a layer of ice 400 feet thick per year. This energy is equal to one watt per square inch of the earth's surface.

Artificial sources most commonly used are carbon, mercury and tungsten and to a less extent iron and graphite. To ignite them and maintain them in incandescent state in which they emit the best of their radiations, electric current is found to be most useful. If resistance is contrived in the course of the electric current, heat is produced to overcome resistance. This ignites the resisting substance and disturbs the electrons in its atomic systems, producing electro-magnetic waves. This stage can be produced by any method of heat, but, to maintain that stage with full control, electricity is the best agent known at present.

Carbon.—This substance was the first and most commonly used in artificial sunlight. It is the best imitation of sunlight known at present and there should be no wonder at it as carbon the all-essential element of living organisms is really the storehouse of solar energy. It stored sunlight when it primarily existed as vegetable life on the face of the earth. That stored sunlight becomes manifest again when carbon is ignited. Finsen used it in local treatment of lupus and also for general treatment. Its spectrum is continuous. Its range of spectrum

is from 2,900A to 50,000A. Its spectrum can be varied by introducing different substances in its core. Some of the substances commonly used for this purpose are iron, tungsten, and cobalt. The special spectra of these substances would be added to that of the carbon. Some would lengthen the spectrum of the ultra-violet side and some on the infra-red side.

Mercury.—Its spectrum is discontinuous as many wave-lengths are absent. It is very rich in the short wave-lengths in the ultra-violet region. The shortest wave-length obtained is about 2,000A. It contains a large amount of infra-red rays too.

Tungsten.—This gives a continuous spectrum embracing the solar spectrum and extending as far as 2,000A. It is rich in ultra-violet and infra-red rays. The output of radiation though small is constant.

Iron and graphite serve a good purpose as generators of infra-red rays.

Actions.—The basis of ray therapy is the absorption of radiations. On absorption they are converted into heat energy, chemical, mechanical or electric energy, or perhaps into some unknown form. The effects are produced at the point where they are absorbed. We must therefore know how far each of the rays penetrate the skin—the only medium through which they are administered. Out of the whole gamut of spectral energy solar radiation is the region of least penetrability. Penetrability increases as we proceed further on either side of the solar spectrum. Cosmic rays are highly penetrative. So are gamma and x-rays. These are on the ultra-violet side. On the other side are the Hertzian waves which are far more penetrating than solar radiations. In the solar spectrum red and short infra-red are the most penetrating, and ultra-violet and long infra-red are the least penetrating. While the visible and short infra-red penetrate to a depth of a few centimetres ultra-violet about 3,000A penetrate the skin about 1 mm. The penetrability of ultra-violet increases as their wave-length increases and so also the visible rays increase in penetration as they increase in wave-length. Penetration may be increased by compression of the skin. 2,000 to 2,500 penetrate up to the horny layer, from 2,500 to 3,200 to the basal layer. 3,200 to 3,900 up to the corium, and 3,900 to 14,000 to the subcutaneous tissue and a little deeper. After 14,000 the penetrability decreases up to 80,000A.

Actions.—The main physiological effects properly understood at present are thermal, chemical, and biological. Approximately they appear in this order in the electro-magnetic spectrum. The thermal effects are most prominent in short Hertzian waves and infra-red rays. Chemical effects are seen in visible and ultra-violet rays, becoming more pronounced in the latter, and biological action begins to appear in ultra-violet rays, increases in x-rays and is

most marked in *gamma* rays. We shall now consider, the therapeutic utility of these actions.

Thermal.—Man is a warm-blooded animal. It is of vital importance to keep the temperature of the body constant at normal, despite variations in outside temperature. This important function is performed by the skin. Life is made possible on earth by its atmospheric envelope maintaining a particular range of temperature on its surface. In the same way the necessary temperature of the human body is maintained by the skin. A variation of 10° on either side of the normal would make life impossible. Heat is being constantly produced inside the body by the innumerable vital processes going on there. If allowed to accumulate this heat would raise the temperature of the body to an intolerable degree. On the other hand there are great variations in the outside air temperature. How subtle and vital must be the mechanism which maintains the normal temperature of the body, in these conditions ! Such a delicate mechanism stands the chances of frequent derangement and so any agent which would be helpful on such occasions must be considered of great therapeutic value. Radiations perform this function best. They recharge the body with vital warmth. These radiations possess the action of selective heating also. Selectiveness in action justifies preference in therapeutics. Different wave-lengths of infra-red rays can heat epidermis, dermis or subcutaneous tissue as desired and short Hertzian waves can heat deeper tissues of the body and different wave-lengths of short Hertzian are supposed to have some selectivity of action on different tissues of the body.

Another effect of thermal rays is the production of hyperæmia. Whenever the body receives injuries by physical, chemical or bacterial agents, the body forces collect together to counteract the harmful effects. This process is called the inflammatory reaction. Hyperæmia is the primary condition in this inflammation. Often this inflammatory reaction is not sufficient. The best known means to assist and supplement this natural reaction is irradiation with thermal rays. It helps the body to give a better and more efficient fight.

Chemical action is production of vitamin D and increase of calcium and phosphorus in blood, and improvement of blood in general with increase of bactericidal and infection-resisting power of blood.

All these biochemical changes collectively signify one important reaction and that is stimulating the hæmopoietic system and defensive mechanism of the whole body against infection.

This body reaction to radiation is a slow process and hence these immunizing forces will be useful to counteract the effects of chronic infections only.

Biological.—One important action is noticed and that is selective action of α -rays and *gamma* rays in destroying rapidly growing cells. This

action is being utilized in the treatment of malignant diseases.

The above described actions are few but very important. Heat regulating function indicates its use in rheumatic conditions. Hyperæmia becomes useful in all inflammatory conditions and in all aches and pains. Biochemical action of stimulating the blood and its defensive properties make the radiation a useful therapeutic agent in anæmia and all chronic infections specially tuberculosis, and biological action justifies its use in malignant diseases. Now rheumatic conditions, inflammations, tuberculosis and chronic infections, rickets and anæmia and malignant diseases make such a large proportion of human ailments that radiations, even if we ignore other beneficial actions of rays, deserve a very honourable place in the field of therapeutics.

After this general consideration of the principal action of radiation a brief survey of the characteristics of each group of rays will be useful, to make the proper selection of rays for therapeutic purposes. Cosmic, radium, α -ray and short Hertzian waves each constitute a special branch in themselves and we had better limit our description to the spectral range of solar radiations only.

1. *Infra-red.*—The spectral range is from 7,700A to 100,000A. From 7,700A to 14,000A, their penetration is the greatest and so therapeutically this is the most useful range. After 14,000A their penetrability goes on decreasing, and they heat only the superficial layers of the skin.

Sources. Sun or any hot body. Commonly used radiators are tungsten, carbon, graphite and iron.

Action. Heat regulating, stimulating skin and sweat glands causing hyperæmia in skin and subcutaneous tissues, and analgesic action; therapeutic uses chiefly due to penetrative properties and thermal action.

2. *Visible.*—Its spectral range extends from 3,900A to 7,700A. This is composed of seven colours. Our knowledge relating to this range is scanty and empirical. Red is supposed to be stimulant and irritant, the blue depressing and sedative, and the yellow reactive on the gastrointestinal tract. Sources are the sun and any incandescent substances. Commonly used radiators are carbon and tungsten.

3. *Ultra-violet.*—Its spectral range is from 200A to 3,900A but in therapeutic use are those from 2,400A to 3,900A. This group has been more studied and is better understood than the other groups. Its different sections are known to have specific actions, *viz*,

- (1) Erythral range extends from 2,400A to 3,100A. The minimum action is at 2,800A and maximum at 2,970A.
- (2) Pigmentation range from 2,900A to 3,300A.
- (3) Vitamin-D production range from 2,800A to 3,100A.

(4) Coagulating albumin range from 2,490A to 3,020A.

(5) Bactericidal range from 2,100A to 2,960A.

Sources are sun, carbon, tungsten and mercury.

The action is mainly biochemical. Vitamin-D production and improvement of calcium metabolism, stimulation of hæmopoietic system and increase of bactericidal and resisting power against infection are the main effects for which ultra-violet irradiation is used.

Dosimetry is the most difficult and complicated part of ray therapy because it has to deal with invisible agents which are not accurately known, whose action is partially understood, whose production in uniform quality and quantity is difficult and which by their very nature are not easy to measure, and to which every individual patient offers a varying resistance. Difficulty caused by absence of measuring standards is further increased by variation of effects of rays in various quantities; mild doses have a stimulating effect, moderate ones an inhibitive, and strong doses a destructive effect. For these reasons it becomes essential to pay special attention to the following factors :—

1. Source of radiation.

(a) Emission factor. Which gives range of wave-lengths emitted.

(b) Maxima. Temperature point when greatest output of radiation occurs.

(c) Radiation area. Which gives quantity of radiations emitted.

As it is not possible to determine these factors in the case of the sun, we have to measure the radiations at the spot where we want to use them. This would require a special helio observatory.

2. Filtering and supplementing of rays.

As there are no known sources which emit the required kind of rays only, we have to filter out the rays which are not wanted and supplement those which are deficient.

3. Distance between the patient and the source of radiation.

Except for the sun this has an important bearing on the intensity of radiations which varies inversely as the square of the distance. If it is 1 at the distance of one foot it will be $1/4$ at the distance of 2 feet and $1/9$ at the distance of 3 feet.

4. Time of irradiation.

This is determined separately for each patient according to the sensitivity of his skin. The skin reaction is empirically classified in four grades. This erythema value of skin sensibility is the best guide known at present to determine the beginning dose as well as the future increment of dose necessary to have the best result.

5. Area of skin exposed.

A small dose should be given if a large area is to be exposed and a large dose can be given if a small localized area is to be irradiated.

6. Sensitiveness of the patient.

This is the most essential part in dosimetry, but unluckily much attention is not given to it. Systematic study of this part of the subject is of utmost importance.

The reaction of human skin to radiation is not uniform. It varies in different individuals. Variations in radio-sensitivity range from 1 to 75 or even 1 to 400. The result is that radiation which is mild for one man may be quite strong for another. The best guide will be to test the skin reaction to particular radiations in different graduations of time and put some value to different reactions. In fact, production of erythema has been adopted as a basis of appraisal. This erythema basis of classification of skin is a most important and practical guide known at present. Dr. Saidman's sensitometric test of exposing the skin from 1 to 18 minutes and classifying the reaction of erythema and pigmentation in four grades is one of the most useful means of guidance at our disposal at present. In fact erythema and pigmentation are two guiding stars for the radio-therapist. Age, sex, occupation, quality of skin, part of body to be irradiated, pathological conditions and medication are some of the factors which affect the toleration of the body to the radiation. Instead of doing guess-work over all these factors, it will be far better to determine the dose in accordance to the erythema and pigmentation value.

It may be generally stated that the solar energy which comes to the earth's surface has made the earth what it is, including the life on it. That which made life can mend it best. The solar radiations therefore may be theoretically taken to be the best radiations for therapeutic purposes. It is impossible to reproduce the solar radiations artificially. No substance is known to produce the solar spectrum. The sun contains all the elements in incandescent state shooting their various radiations in combinations. Even in the case of certain rays which can also be artificially produced the superiority of solar rays is unquestioned. The solar rays coming from an immense distance are parallel and so all of them can be perpendicularly received over the whole irradiated area. The rays from lamps are divergent from the central source and so oblique, except in the centre. The solar radiations cost nothing. The lamps are so costly. Moreover they are best worked by electricity. They cannot therefore be availed of in places where electric current is not obtainable. In a tropical country where strong sunlight is available for at least 9 months in the year solar energy should be utilized to the utmost.

In a poor country like India the economic aspect of their use enhances their value much more. A structure designed to make the most scientific use of solar rays for therapeutic purposes is the most welcome thing and when it combines efficiency with large scale operations it should recommend itself to all public bodies who have to think and arrange for medical relief

of the large population. Dr. Saidman's design of the solarium answers all these requirements. We have recently constructed a small solarium containing two cabins. It can be used anywhere as it does not require electric current for its operation.

The solarium has been specially designed to enable us to make the best possible therapeutic use of solar radiations. It is built sufficiently far from the city to ensure that the dust which generally rises over a busy town is reduced to the minimum in the atmosphere through which the radiations come to the solarium. By raising it to a height of about 40 feet the dust nuisance is further reduced. The platform on which the solarium cabins are built is mounted on a tower at a height of about 30 feet from the ground which space is filled up by a fixed octagonal masonry structure which is utilized for artificial-ray therapy and for office purposes. The platform is 114 feet long, 10 cabins are built on it each about 13 by 9 feet. These cabins are equipped with all the necessary appliances for sun-ray treatment. In the centre of the platform on one side are the lift and the staircase and on the other is the observatory. To keep the cabins facing the sun an electric motor has been attached to the tower by which the tower is made to revolve in a horizontal plane. It can make a complete round in 30 minutes. As it is essential that the rays must fall on the patient perpendicularly a further adjustment in the vertical plane is necessary. This is obtained by cabin beds which revolve vertically. By means of these two arrangements the sun's rays can be focussed perpendicularly on the patient at any time of the day. The cabins have single bed arrangements. Each cabin has large windows. On the roof there are two sliding lids one of glass and the other of sheet iron. To the bed are attached large concentrators which concentrate three to five times the sun's rays which enter through roof and window. Finsen first used lenses for concentration. Below these concentrators the necessary filters are placed in order to cut off the unwanted rays. Round about the beds are placed lamps which can be used to supplement the natural radiations if necessary. There is an air-cooling arrangement near the sofas. In each cabin there is a bathroom with shower bath arrangement.

The observatory is a very important part of the solarium. There is a separate meteorological observatory where the atmospheric conditions of temperature, pressure and humidity, clouds, winds, etc., are observed and recorded. In the front part of the solarium observatory there is an ingenious contrivance to detect the slightest variation in the facing of the solarium to the sun. This variation can be corrected by revolving the whole solarium in the direction of the sun. The sun's position in the sky is constantly changing during the day and so the solarium has to be adjusted accordingly every five or ten minutes. The solarium observatory

contains several helio-actinometers for the constant measurement of the intensities of the sun's total radiations of infra-red and ultra-violet rays. Their readings are recorded every half hour. To avoid frequent calculations of the time of exposure due to the variations in the intensity of solar radiations, a special counter-helio-actinometer is fitted in which electric current is produced in proportion to the intensity of radiation. This current moves a small motor. The revolutions of this motor are recorded on a dial with unit marks. The needle moves slowly or briskly according to the motion of the motor which depends on the intensity of the radiations. One unit motion of the needle takes about 15 minutes at noon on clear days. This time is lessened or increased if the intensity of solar radiation increases or diminishes.

A special spectroscope with film arrangement is continually taking photographs of the solar spectrum. There is a konimeter to count dust particles in the atmosphere. A sunshine recorder continually records the hours of sunshine and its intensity during the day. The switch-board for the control of all the cabins is kept in the observatory.

The measurement of the skin sensitivity is as important as the measurement of radiations. Skin sensitivity tests are taken of every patient by a special instrument called the skin sensitizer. It enables us to note the erythema and pigmentation reaction of the skin caused by exposures from 1 to 18 minutes. The electro-thermometer records the minutest variations in the temperature of the skin in different regions of the body. There is a complete equipment of artificial source of radiations for general and local treatment. There are two apparatuses for production of short Hertzian waves, one with an arrangement for production of short Hertzian waves of 24 metres and the other for 6-12-18-24 metre waves and artificial fever. There is a unit for deep x-ray therapy. There is also a radium department with 475 milligrammes of radium; appliances for physiotherapy, electrotherapy and heat therapy have been recently added.

As the solarium is equipped with all the means at present available for the therapeutic use of the various kinds of radiations, we are justified in naming the solarium, the institute of poly-radio-therapy.

To commemorate its celebrated founder, we have named the institute after him—Ranjit Institute of Poly-Radio-Therapy.

Climate of Jamnagar

The description of Jamnagar Solarium will not be complete without a few words about the climate of Jamnagar. In its atmospheric aspects, Jamnagar, though a little inland, may be said to be a seaside place. It is 57.37 feet above sea level. It has sea to the north and west of

it. Its climate is moderate, the maximum temperature going to 104.5°F. in May and the minimum to 44°F. in January. The average rainfall is about 23 inches. Out of 365 days of the year on average there are 280 clear days, the remaining 85 are more or less cloudy, on an average for 2 to 4 hours a day. The maximum quantity of ultra-violet rays is recorded in May and June and minimum in July and August. The maximum amount of ultra-violet rays is obtained between 11 a.m. and 1 p.m. during the day and minimum after 3-30 p.m., from 8-30 to 11 in the

morning and 1 to 3-30 p.m. in the afternoon, they are available in moderate quantities.

The counts of dust particles show that in the evening there is an increase of dust particles in the atmosphere from 5 to 50 per cent.

During the four years of its existence we have treated about 10,000 cases. The largest number of cases were of rheumatism, surgical tuberculosis and skin diseases, superficial infection, deficient calcium metabolism and paralysis. The results in leucoderma, elephantiasis and asthma are encouraging.

THE PARKES MEMORIAL PRIZE, 1938

IN the absence of any recommendations for the award of the Parkes Memorial Prize for the year 1938, the committee administering this prize fund has decided to withhold the award for the year referred to.

The Parkes Memorial Prize consisting of a gold medal and £30 is awarded annually to the officer who is considered by the committee to have done most to promote the advancement of naval or military hygiene.

In awarding the prize for 1939 (and thereafter until further notice) first consideration will be given to original articles or reports of investigations of value from the point of view of naval or military hygiene, and published in one or other of the various medical journals.

The prize is open to medical officers of the Royal Navy, Army and Indian Army, with the exception of the teaching staffs of the Royal Naval Medical College, Greenwich, the Royal Army Medical College, London, and the Army School of Hygiene, Aldershot.

BOMBAY MEDICAL COUNCIL

THE following extracts from a summary of the proceedings of the meeting of the Bombay Medical Council held on 6th February, 1939, are published for information:—

Before the commencement of the proceedings, the President moved from the Chair and it was agreed that the Council put on record their sense of the loss suffered by the death of Dr. Rajabally V. Patel, who had been a member of the council from the beginning.

The council proceeded to consider the application of Mr. M. S. J. DeSouza, retired military sub-assistant surgeon, for the restoration of his name to the Bombay Medical Register and resolved that his name be restored to the register.

The council proceeded to consider the question raised by the Bombay Medical Union whether, in view of clause (j) of rule 1 in section II of the Code of Medical Ethics, a registered medical practitioner can attend, in response to a manufacturer's invitation, at functions wherein scientific films, etc., are shown by firms or manufacturers or their agents or where trade medical films are exhibited by medical associations, and it was resolved that so long as no reference is made to any proprietary product, it is not in contravention of clause (j) of rule 1 in section II of the Code of Medical Ethics for medical practitioners to attend any such functions.

The council proceeded to consider an allegation against Mr. Chimanlal L. Amin, M.B., B.S., that a certain vaccination certificate and an anti-cholera inoculation certificate given by him to a passenger were not true, and, after taking into account the results of the enquiries made in regard to the marks of the vaccina-

tion and anti-cholera inoculation, what serum was used for the inoculation, how he made sure about the identity of the person concerned, how long the person was known to him, etc., it was resolved that Mr. Amin be warned to be more careful regarding the identity of the persons to whom he gives certificates.

The council proceeded to consider a motion made by Mr. U. B. Narayanrao (1) that Government be recommended to pass an enactment penalizing those using the prefix 'Doctor' or 'Dr.' other than by registered medical practitioners and those holding a doctorate of a recognized university and (2) that the council appoint visitors to attend and be present at the professional examinations required for obtaining the qualifications of the licensing bodies in this province, and it was resolved, as regards the first proposal, that as the point raised therein is already covered by the Bill to Prohibit the Conferment of Unauthorized Medical Degrees, etc., and Assumption thereof, no further action is necessary in respect of this proposal. As regards the second proposal, it was resolved (1) that, so far as the medical examinations of the Bombay University are concerned, it be suggested to the Medical Council of India that they may associate two nominees of the Bombay Medical Council with the inspectors appointed by the Medical Council of India to inspect the medical colleges in the province of Bombay, and that, should the Medical Council of India not agree to the above suggestion, the Bombay Medical Council should appoint their own visitors to be present at the university medical examinations, and (2) that, with regard to the examinations of the College of Physicians and Surgeons of Bombay, the question be considered along with the other items suggesting the appointment of visitors to attend and be present at the examinations of the D.O.M.S. and the D.G.O. of the college.

The council proceeded to consider the following reply received from Government with regard to a previous resolution of the council (*viz.* that the council is of opinion that the practice of getting countersignature on medical certificates granted by registered medical practitioners is against the principles and spirit of the Bombay Medical Act, VI of 1912 [section 10(2)], and recommend to Government to put a stop to this practice):—

Government's reply.—'Medical certificates granted by registered medical practitioners recommending leave to Government servants are ordinarily accepted by Government and the heads of Government offices in this province, provided that the certificates are in the form prescribed by Government. It is only in special cases where an excessive amount of leave is recommended, or where the head of the office has special reasons that the right of calling for a second medical opinion from the presidency surgeon or the civil surgeon is exercised. In the circumstances Government is unable to accede to the request made by the Bombay Medical Council'.

And it was resolved that Government be requested to inform the officers to whom medical certificates are referred that they should comply with rule 8 in section II of the Code of Medical Ethics, which is quoted below:—

'S. When it becomes the duty of a practitioner occupying an official position to see and report upon a case of illness or injury, he should communicate with the practitioner in attendance, so as to give him the option of being present. The practitioner seeing the case officially should scrupulously avoid interference with, or remark upon, the treatment or diagnosis that has been adopted.'

The council proceeded to consider the requests for the recognition of the D.O.M.S. and the D.G.O. of the College of Physicians and Surgeons of Bombay for registration as additional qualifications and inclusion in Table (G) given in the Bombay Medical Register and, dealing with the proposals of the executive committee for the appointment first of visitors to attend and be present at the examinations for these qualifications, it was resolved that the following visitors be appointed to attend and be present at the examinations for the L.C.P.S. of the college:—

The President .. For surgery, midwifery and examination for the D.G.O.

Dr. P. C. Bharucha .. For medicine.

Messrs. C. J. Ghia and V. D. Sathaye. For ophthalmology and examination for the D.O.M.S.

The council proceeded to consider the application received from Mr. Rajekhan for permission to be registered under section 7(3) of the Bombay Medical Act, VI of 1912, and it was resolved that Government be informed that, in the opinion of the council, Mr. Rajekhan be given permission to be registered under section 7(3) of the Bombay Medical Act, 1912.

The council proceeded to consider the draft Bill to Provide for the Registration and Inspection of Nursing Homes received from Government for the opinion and suggestions of the council and it was resolved that the Bill be approved, subject to certain alterations suggested therein by a sub-committee appointed to consider and report on the subject and by the executive committee.

The council proceeded to consider a Government letter asking for the advice of the council whether certain medical graduates of the Tilak Maharashtra Vidyapeeth, Poona, or any of them, should, in view of the circumstances mentioned by Government, be registered under the Bombay Medical Act, 1912, and it was resolved that under the provisions of the Bombay Medical Act, 1912, the practitioners mentioned by Government cannot be registered.

The council proceeded to consider a Government letter regarding the question of reservation of seats for the province of Sind on the Bombay Medical Council and it was resolved that the Government of Sind be allowed to nominate two representatives on their behalf for nomination as members of the Bombay Medical Council.

The council proceeded to consider a Government letter in connection with the proposal that it be urged again on the Government of Portuguese India that all medical practitioners registered under the Bombay Medical Act, 1912, should be permitted to practise medicine in Portuguese India on a reciprocal basis, and, after taking into account the circumstances mentioned by Government, it was resolved that the matter be dropped.

THE BIRTH CONTROL RESEARCH COMMITTEE

THE Secretary, Birth Control Research Committee of Vile Parle, informs us:—

The number of people who visited and sought advice at the Birth Control Centre at 166A, Vincent Road, Dadar, Bombay, conducted by the Birth Control Research Committee of Vile Parle, during the quarter ending 15th March, 1939, was 1,140 out of which 625 were males and 515 were females,

NUTRITIVE VALUE OF INDIAN FOODS

THOSE who want to plan diets either for themselves or for others will find their task made easy by *Health Bulletin No. 23* on 'The Nutritive Value of Indian Foods and the Planning of Satisfactory Diets', a second edition of which has just been brought out.

Data have been collected about the composition of some 50 more foodstuffs and added to the analyses of some 200 common Indian foodstuffs previously given. While there is room for further studies of special varieties of foodstuffs which are consumed in remote localities and have a purely local distribution, nearly all the common and familiar foodstuffs of India have now been investigated.

The publication is a part of the move to popularize the results of nutrition researches. In the early years of nutrition work, the first objective was to get together the scientific data on which practical work could be extended to the homes of the people. This material has since been collected by the workers at the Nutrition Research Laboratories, and is now being made available to the public.

Prefaced by a summary of modern ideas about diet, an account is given in the *Bulletin* of calorie requirements, and standards suitable for the various age and sex groups in India are suggested. Next, protein, fat, and various vitamins and minerals are dealt with, with special emphasis on the minimum requirements of each.

It is advisable, says the *Bulletin*, that those who are responsible for the institutional care of children, etc., and all who are concerned with practical nutrition work, should have some idea of the effects on the body of a diet which is ill-balanced and defective... e.g., of a diet which is largely composed of milled cereals and contains an insufficiency of proteins, mineral salts and vitamins, and which calls for improvement. There is a long list of diseases, common in India, due in some way or other to dietetic causes. Such are: beri-beri, certain anæmias of pregnancy, keratomalacia, osteomalacia. States of malnutrition which fall short of serious disease are widespread.

A well-balanced diet is essential if growth and development are to take place normally. The frequency of minor ailments in school children can be reduced by improving the diet. But well-balanced diets are in general more expensive than deficient ones. It is on this point that the nutrition worker encounters the main difficulty. Those who suffer from under- and mal-nutrition usually cannot afford to purchase a satisfactory diet. But even when poverty prevents the purchase of a diet which satisfies modern standards of nutrition, it is often possible to make effective improvements with little increase in cost, and how these improvements can be effected are indicated.

Information is given in tabular statements about protein, fat, carbohydrate, fibre, calcium, phosphorus, iron, calories and vitamins, and appendices are added with data about the biological value of the proteins of various foods and the availability of iron in certain foodstuffs.

Stress is laid on the value of what are called the 'protective' foods.

Human beings, and particularly children, cannot thrive at their best on a diet largely composed of cereals such as rice, millet, etc., and insufficiently supplemented by other foods. To make good the deficiencies of such a diet, they must consume fair quantities of foods like milk, green vegetables, eggs, fruits, etc. These are sometimes known as the 'protective' foods, since they are rich in proteins, vitamins and mineral salts, and protect the body against the ills which result when the diet is largely based on less nutritious foods, such as milled rice. Cod-liver oil, which is very rich in vitamins A and D, may be classed as the most valuable 'protective' food.

In general, diets in India are defective because they do not contain 'protective' foods in sufficient abundance. The aim in public health nutrition work in general, and planning 'well-balanced' diets, must be to increase intake of 'protective' foods. The classes in the community which are particularly likely to

suffer if their diet is defective are infants and growing children, and expectant and nursing mothers.

It is not only the poor, whose choice in the matter of food is extremely limited, who are ignorant and prejudiced about diet. Many people in India and elsewhere, who could afford to consume and feed their children on an excellent diet, do not in fact do so. One can readily find among children of the more prosperous classes cases of serious malnutrition and food deficiency disease.

In drawing up a new diet schedule, or in assessing the value of an existing schedule, it is essential to know whether enough food is being provided. It might be thought that it is easy enough to discover food deficiency, for such deficiency must cause hunger. But experience has shown that human beings can adapt themselves, at a low level of vitality and with their powers impaired, to an insufficient ration, and scarcely realize that they are under-fed. The nutrition worker, in setting up standards of food requirements, ignores this remarkable faculty of the body to adapt itself to semi-starvation. His standard of food intake implies full satisfaction, enough to enable human beings to lead an energetic life at a reasonably high level of working capacity.

There are, of course, many kinds of public health nutrition work besides the planning of adequate diets. The task of the nutrition worker is often to make special additions (e.g., milk, cod-liver oil, various vitamin-rich preparations) to an unsatisfactory diet rather than to plan the whole diet afresh. Infant feeding is a subject demanding special knowledge and training. But in all branches of practical dietetics the fundamental principles involved are the same, and an understanding of them is essential for successful work in this field.

The first edition of this *Bulletin* had a wide circulation in India. The low cost (2 annas) brought it within the reach of an extensive circle of readers. About 25,000 copies have been sold, a figure indicating a popularity rarely achieved by public-health bulletins.

The second edition retains the price of the first. Corrections necessitated by advancing knowledge have been made here and there and a few passages have been clarified in the light of experience gained during the distribution of the first edition.

At the special request of a number of readers, a section dealing with infant feeding, including dietary requirements of infants, breast feeding, artificial feeding, weaning and the difficulties of infant welfare work in practice, has been added. In 1935 about 1,250,000 Indian infants died before reaching the age of one year. A high percentage of these deaths was due to malnutrition.

Another useful addition is a list of Hindustani equivalents for the names of most of the foodstuffs.

THE CHOLERA DANGER AND THE NECESSITY FOR USING GENUINE VACCINE

IN 1938 the attacks and deaths from cholera in British India, as recorded in the office of the Public Health Commissioner, totalled approximately 323,243 and 158,010, respectively. The worst affected provinces were the United Provinces with 70,000 cases and 34,000 deaths, the Central Provinces with 94,000 cases and 43,000 deaths and Bengal with 86,000 cases and 45,000 deaths. The Punjab reported 8,600 cases and 4,600 deaths during the same period.

This grave incidence of cholera has been a matter of serious concern to the country and the subject came under exhaustive discussion at the Medical Research Conference held in Delhi in December and at the second meeting of the Central Advisory Board of Health in Madras in January.

Recent research work under the Indian Research Fund Association has thrown new light on the nature of the cholera organism. It has been shown that there are in nature many organisms which resemble the cholera organism but do not cause the disease. The value of inoculation against cholera is now generally

recognized and the number of inoculations carried out in India shows a large regular increase over the last few years. It is, therefore, of the greatest importance that the vaccine used for protection against cholera should be prepared from the genuine cholera organism.

The Central Advisory Board of Health at its meeting in January recommended that this fact should be made widely known throughout India, not alone to health officers, medical officers and private medical practitioners, but also to the general public.

The Cholera Advisory Committee of the Indian Research Fund Association considered the question of the sources of supply and nature of anti-cholera vaccines used in the several provinces in India. The vaccines used are obtained from (a) laboratories under the control of the Central and Provincial Governments or their Public Health Departments, and (b) commercial firms.

Examinations carried out on cholera vaccines available in the market in India during the last 18 months have indicated that in certain cases these vaccines were not prepared from the strains of the true organism. The view of the Cholera Advisory Committee, which was accepted by the Medical Research Conference, is that no protection against cholera can be expected from the use of such vaccines.

It is, however, by no means certain that those engaged in the manufacture of anti-cholera vaccines are all sufficiently acquainted with recent bacteriological findings. It would be disastrous if the people of India lost their belief in the value of anti-cholera inoculations. It is therefore the duty of all health officers, medical officers and private practitioners to ensure that the cholera vaccine they use possesses a high protective value. With that object, they should assure themselves that it is manufactured from a suitable strain of organism in accordance with the recommendation made in 1936 by the Cholera Advisory Committee regarding the technique of manufacture of cholera vaccine and the strains to be used.

For the purpose of ensuring that the vaccine is made from correct strains it is recommended that those employed in the manufacture of the vaccine in India should be strains tested and issued by certain specified laboratories which have been continuously engaged in the study of the cholera vibrio. The Directors of the Central Research Institute, Kasauli, the Calcutta School of Tropical Medicine and the King Institute, Guindy, have expressed their willingness to issue suitable strains to all laboratories, including those of commercial firms, for this purpose.

Copies of the recommendations made by the Cholera Advisory Committee in 1936 are available on application from the office of the Public Health Commissioner with the Government of India.

INDIAN MEDICAL COUNCIL

IN exercise of the power conferred by clause (a) of sub-section (1) of section 3 of the Indian Medical Council Act, 1933 (XXVII of 1933), the Central Government is pleased to nominate Lieutenant-Colonel T. C. Boyd, M.R.C.P. (Irel.), F.I.C., F.R.C.S. (Irel.), D.P.H. (Irel.), I.M.S., Officiating Surgeon-General with the Government of Bengal, to be a member of the Medical Council of India, from Bengal, with effect from the 30th March, 1939, *vice* Major-General P. S. Mills, C.I.E., I.M.S., resigned.

THE FACULTY OF TROPICAL MEDICINE AND HYGIENE, BENGAL

THE following students are declared to have passed the D.T.M. Examination, Session 1938-1939:—

Passed

(Arranged in alphabetical order)

1. Abu Mozaffar Noosin, M.B. (Cal.), private practitioner.
2. Hari Pado Banerji, M.B., B.S. (Lucknow), private practitioner.

3. Dharendra Kishore Bhattacharjee, L.M.F. (Dacca), Assistant Medical Officer, Mazengul Tea Estate, Assam.
4. Des Raj Bowry, L.S.M.F. (Punjab), Sub-Assistant Surgeon, N. W. Railway.
5. Panchanon Chatterji, M.B. (Cal.), private practitioner.
6. Satya Ranjan Chatterji, M.B., B.S. (Patna), D.P.H. (Cal.), private practitioner.
7. Devaprasad Choudhury, M.B., B.S. (Patna), D.P.H. (Cal.), School Medical Officer (temp.), Bhagalpur Division, Bhagalpur.
8. Nikhil Ranjan Das Gupta, M.B., B.S. (Patna), private practitioner.
9. Joseph Michael Francis D'Mello, Diploma Medical College, Madras, I. M. D., Military Assistant Surgeon, Government of India.
10. Indar Sen Jetley, M.B., B.S. (Punjab), Professor, Gurukul Kangri Ayurvedic College, Haridwar.
11. Wazir Chand Jolly, L.S.M.F. (Punjab), L.T.M. (Cal.), private practitioner—Awarded the 'Chuni Lal Bose' Gold Medal, 1939.
12. Shanker Das Kapur, M.B., B.S. (Lucknow), private practitioner.
13. Kimsong Siambhakdi, M.B. (Siam), Medical Officer, Department of Public Health, Siam.
14. Jagdish Sahai Mathur, M.B., B.S. (Lucknow), private practitioner.
15. Md. Khayber Hossain Khan, M.M.F. (Cal.), private practitioner.
16. Md. Sunawar Ali Laskor, M.B. (Cal.), private practitioner.
17. Mohammad Abu Zaffar, M.B., B.S. (Patna), private practitioner.
18. Mohammad Abdur Rahman, M.B., B.S. (Punjab), Sub-Assistant Surgeon, Punjab Subordinate Medical Service.
19. Hugh Archer Murphy, Diploma, Grant Medical College, Bombay, I. M. D., Military Assistant Surgeon, Government of India.
20. Joseph Pereira, M.B., B.S. (Madras), private practitioner.
21. Prayaga Venkatesam, M.B., B.S. (Vizag Medical College), private practitioner.
22. Asutosh Purkayastha, M.B. (Cal.), private practitioner.
23. Nityanirajan Roy, M.B. (Cal.), private practitioner.
24. Daya Shankar Shukla, M.B., B.S. (Lucknow), private practitioner.
25. Brahma Nand Singh, M.B., B.S. (Patna), private practitioner.
26. Sudhir Chandra Som, M.B., B.S. (Patna), D.P.H. (Cal.), private practitioner.
27. Godwin Lionel Robbins Tapsall, M.R.C.S. (Eng.), L.R.C.P. (Lond.), I. M. D., Military Assistant Surgeon, Government of India.
28. Tribeni Prasad, L.M.F. (Rangoon), L.T.M. (Cal.), Sub-Assistant Surgeon, Burma Railways.
29. Pranlal Ranchhodlal Trivedi, L.C.P. & S. (Bom.), L.T.M. (Cal.), Medical Officer-in-Charge, Infectious Diseases Hospital, Ahmedabad Municipality.
30. Ruth Frances Wordsworth, M.R.C.S. (Eng.), L.R.C.P., D.P.H. (Lond.), private practitioner.

Current Topics

Alcoholic Intoxication and Pneumococcal Infection

(From the *Journal of the American Medical Association*, Vol. CXII, 21st January, 1939, p. 240)

CLINICIANS have observed for many years that alcoholic intoxication is a predisposing cause of pneumonia and that the death rate in pneumonia in alcoholic addicts is definitely higher than the mortality of abstainers from alcohol. Osler believed that the most potent predisposing factor in pneumonia is the lowered resistance due to alcohol. A most convincing clinical report on alcohol as a predisposing factor in pneumonia was published in *The Journal* fifteen years ago by Capps and Coleman. Among 3,422 cases of pneumonia at Cook County Hospital in Chicago they found that the mortality rate among the excessive drinkers was 49.87 per cent, among the moderate drinkers 34.4 per cent, and among the abstainers or occasional drinkers 22.45 per cent.

Medical literature contains many reports of both clinical and experimental observations which point strongly to the fact that alcoholic intoxication lowers the resistance not only to pneumococcal infections but to other infections as well. This literature has recently been reviewed by Pickrell of Johns Hopkins University. In 1884 Robert Koch reported observations that during cholera epidemics most of the people who became sick had been guilty of alcoholic excess. Koch followed his clinical studies by experimental work, in which he showed that intoxicated rabbits died sooner of cholera than did similarly infected non-intoxicated animals. Abbott demonstrated that the resistance of rabbits to infection by *Streptococcus pyogenes* was diminished through the influence of alcohol and that the susceptibility of such animals to certain other types of infection was increased by alcoholic intoxication. Laitinen demonstrated unmistakably the deleterious effect of alcohol on the resistance of animals to anthrax; practically all his alcoholized animals died of anthrax,

whereas most of those that had not been given alcohol recovered. In reviewing the literature, Pickrell was impressed by the fact that few of the studies had been adequately controlled and that none of them gave a satisfactory explanation for the effect apparently brought about by alcoholic intoxication. He therefore devised and with the assistance of Dr. Arnold R. Rich carried out an extensive series of experiments in an attempt to discover the mechanism by which this occurs.

In brief, the experiments consisted of immunizing rabbits by intravenous injection of type I pneumococcus serum, then of intoxicating some of them with ethyl alcohol until stuporous and then of infecting all of them and the control animals with the same dose of type I pneumococci injected into the skin. In a type experiment twelve rabbits were immunized against type I pneumococci. In a few hours intoxication with alcohol was induced in six of these animals, and all of them, as well as the control animals, were injected in the flank with 0.1 c.c. of an eight hour type I pneumococcus culture. In four hours the non-immunized rabbits gave a positive blood culture and all such animals died within eighteen hours. The immunized rabbits which had been intoxicated showed a positive blood culture at from nine to ten hours and death occurred within twenty-four hours. The immunized rabbits which were non-intoxicated did not develop a positive blood culture and they survived. The immunized group which had not become intoxicated developed only a minute erythematous lesion at the site of injection. The non-immunized rabbits which had not been intoxicated developed about the site of injection a large purpuric, oedematous, hyperæmic lesion which extended to the belly surface. In striking contrast, no macroscopic lesion developed in any of the intoxicated rabbits at the site of the injection. In all the non-intoxicated animals microscopic examination revealed a dense leukocytic infiltration at the sites of injection but in the intoxicated rabbits there was practically no leukocytic emigration, and bacteria swarmed in the tissues

marked local and systemic reaction. Particular foods likewise frequently play a similar rôle.

The recognition of food allergy in these cases necessitates use of the test diet method of study. Cutaneous tests yield misleading information. Both false positive and false negative reactions are obtained. It is frequently necessary to repeat the test diet studies in order to demonstrate the mechanism in a given patient. Negative results at one time may give way to clear-cut and predictable response to the successive exhibition and withdrawal of a particular food a few weeks or months later. The reactivity of the colon therefore exhibits a phasic variation in this respect, apparently corresponding to successive periods of sensitization and desensitization. In some instances evidence of food allergy is obtainable during periods of activity of the disease. In others this factor is demonstrable only in the early stages of recurrence.

Satisfactory allergic studies were completed in sixty-seven cases. Classification was based on the subjective phenomena reported by the patient and more particularly on the appearance of the mucous membrane of the rectum and the rectosigmoid at repeated proctoscopic examinations after each change in diet. Clinical evidence of active food allergy was obtained in forty-four cases. In seven others the evidence was equivocal. A history of allergic disease in the patient or in the patient's family was not a common finding. Idiosyncrasies to certain foods have been noted by about half of the cases. In the order of frequency, the foods most commonly at fault were milk, orange, wheat, spinach and tomato.

Secondary or conditioned deficiency disease has occurred as a complicating factor in forty-six of the cases. It appears to be the expression of the combined deficit of a number of essential factors. Lowering of the plasma proteins and inversion of the albumin-globulin ratio is not uncommon. The blood calcium is frequently below normal levels. The vitamin A and vitamin C values are often low, and it is probable that certain of the other vitamins are similarly affected.

These mixed deficiency states appear insidiously and gradually assume increasing significance. They may play a most important rôle in the course of the disease and in the more severe cases may determine the outcome. Recognition of this complication and intensive therapy is essential.

COMMENT

These observations have led me to certain conclusions concerning the mechanism of chronic ulcerative colitis. The evidence so far available does not justify the hypothesis that the disease is a specific infection resulting from the primary action of a single specific micro-organism. On the contrary, there is much evidence to indicate that it may be initiated by any one of a number of bacteria, known to be pathogenic and known to produce inflammatory lesions in the colon. Once the mucosal barrier has been broken by such an agent, secondary infection necessarily occurs. The secondary invaders will naturally include certain of the bacteria present in the colonic contents. Sections of colon removed surgically or at autopsy and stained for bacteria reveal Gram-negative bacteria in the more superficial portions of the affected tissue and Gram-positive organisms in the deeper levels. Under such conditions it is not remarkable that conflicting observations have been recorded, nor is it remarkable that special methods will yield certain types of bacteria in significant numbers. Both types of observation are factual. Unfortunately they have tended to create dissension rather than progress.

The phenomena of the disease appear to result from the combined action of a number of factors. There is infection, probably always mixed in character, of the affected portion of the wall of the colon. Both the secretory and the motor physiology of the gastrointestinal tract are adversely and variously affected. Sensitization of the colon to foreign protein of bacterial and dietary origin plays an important rôle in the mechanism of relapse and activity of the disease. Not

infrequently secondary deficiency states occur and assume major clinical importance.

TREATMENT

The medical management of chronic ulcerative colitis must be based on this complex mechanism and it must be guided by the phenomena observed in the particular case. In the past the greatest emphasis has been placed on antibacterial measures. This originated in the concept that ulcerative colitis is a simple infection and that its effects, both pathologic and physiologic, are restricted to the colon. This hypothesis is no longer tenable. The great variety of antibacterial measures advocated bears mute but impressive testimony to the inadequacy of all.

Disturbances of normal physiology must be compensated. Hydrochloric acid in amounts up to 4 c.c. with meals is of definite value in the presence of anacidity. It tends to control distention and flatulence and to curtail the diarrhoea. Sedatives such as phenobarbital and at times opium derivatives are useful in the presence of a hypermotile colon. They are contra-indicated in those cases presenting a slow colon motor rate. In the latter the number of stools and the amount of pain are usually reduced by a properly adjusted daily dose of a saline cathartic and large fluid intake.

Adjustment of the diet to the needs of the patient is essential. A high protein low carbohydrate diet is better tolerated than the conventional high carbohydrate 'colitis diets' traditionally in use. The importance of repeated investigation of the possibility of food allergy by the test diet method cannot be overemphasized.

The vitamin and mineral intake must be maintained at levels above the requirements of the normal individual. This necessitates supplementing the diet by the addition of special sources. Such supplements are essential during periods when the restricted test diets are in use. A constant watch must be kept for the early signs of deficiency disease and when evident they must be strenuously treated.

Autogenous vaccines, if recognized pathogens have been recovered on culture, appear to be helpful when used in conjunction with the other methods of treatment. Evaluation of the effects of vaccine therapy, however, is often difficult, particularly in view of the psychic effect on many patients who strongly believe in their efficacy. On theoretical grounds the rationale for the use of antisera seems less well grounded. I have not been impressed by the results of bacteriophage treatment in this disease.

Certain general measures are applicable. Definite foci of infection should be appropriately treated. Education of the patient to cope more successfully with his psychologic problems is frequently important. The effort to achieve formed stools, especially by the use of bismuth, is ill advised, since it adds to the already complex mechanism—the factor of mechanical trauma to the inflamed mucosa. I believe that the stools should be kept liquid or semi-liquid until healing is complete.

What results are to be anticipated from medical management? It is unfortunate that the word 'cure' has been used in connection with chronic ulcerative colitis. Too frequently it appears as a chronic progressive disease exhibiting periods of spontaneous activity and quiescence. Fifty-one of the patients have had recurrences or have shown continuous activity of the colitis with failure to respond satisfactorily to treatment. It is impossible to say that after any given period of freedom from activity the disease will not recur. In this respect it resembles the problem of pulmonary tuberculosis. It is impossible to be certain from the patient's symptoms or lack of symptoms that healing has actually occurred unless confirmation is obtained by both the sigmoidoscope and the x-rays.

In this respect also the problem resembles that of tuberculosis. Consequently it seems most desirable to borrow from the terminology of the latter disease and to substitute the term 'apparently arrested' for 'cured'.

Twenty-three of the cases are apparently arrested, forty-four are definitely improved but not healed, thirteen are unimproved and death occurred in five.

SURGERY

Prognosis in the individual case depends necessarily on the extent of irreparable damage to the colon and on identification and control of the factors operating to maintain activity of the disease. When extensive anatomic changes have occurred it is vain to hope for restoration to normal. Many such cases constitute serious problems of management. The complications resulting from chronic sepsis are common and, as was the case in two of my fatalities, these complications may lead not only to chronic invalidism but to death of the patient.

In the last few years there has been an increasing tendency to include radical surgery among the available therapeutic measures. The selection of cases and the decision as to when to resort to operative intervention imply the necessity for joint medical and surgical study and supervision both before and after operation. The detailed management of these problems should be carried out under the direct supervision of the senior physician and the senior surgeon of the group. In conjunction with Dr. Henry W. Cave such a detailed and combined approach has been made an integral part of the activities of the Gray Service of the Roosevelt Hospital. This has already been discussed.

Apart from the acute emergencies of impending perforation or repeated massive hemorrhage, surgical intervention should be withheld pending complete evaluation of the particular problem. This entails detailed investigation of the underlying mechanism, decision as to the degree and extent of permanent damage to the colon and the clinical response to conservative treatment. Frequently this requires study of the patient over a period of many months. Failure to achieve clinical improvement, persistence and progression of the lesions as seen at proctoscopy, x-ray evidence of progressive fibrosis of the colon with pseudopolypoid degeneration of the mucosa and the development or progression of the complications attributable to chronic sepsis constitute the elective indications for surgery.

Three operative procedures frequently performed in the past have no place in the management of chronic ulcerative colitis: Appendicostomy, caecostomy and double-barrelled colostomy are based on false premises—the assumption that medicated irrigations will eliminate infection and therefore accomplish cure and that these procedures produce physiologic rest of the colon. These procedures are not curative and frequently are not even palliative. They have the serious drawback of greatly complicating both medical study and treatment and subsequent radical surgery, when and if this becomes necessary.

Elective surgery, therefore, in cases presenting the distal type of colitis and those presenting involvement of the entire colon implies the creation of an artificial stoma proximal to the affected area and subsequent extirpation of the diseased tissue. The comparatively uncommon type of disease in which the lesions are proximal to the sigmoid and in which the lower segment of the colon is normal presents a different set of indications as regards both the choice of procedure and the time for its performance. We believe that operative intervention should not be delayed in these cases. We have observed at least one instance in which extension has occurred downward to involve previously normal lower segment. In this type of case the procedure of choice is early ileosigmoidostomy, with subsequent removal of the diseased portion of the colon.

SUMMARY

The prolonged observation of this series of cases together with isolated observations from many others points to the probability that ulcerative colitis is a chronic disease with an inherent tendency to progression and relapse. It is characterized pathologically by inflammation and ulceration of the mucosa of the colon

and by inflammation and progressive production of scar tissue in the deeper layers of the colonic wall. It is characterized physiologically by secretory and motor disturbances of the stomach, the small intestine and the colon, and at times by disturbed function of other physiologic systems. It appears to result from the action of several different factors operating singly or in conjunction with one another. These include primary infection, which present evidence indicates may be produced by several known pathogenic organisms; secondary infection especially by *Escherichia coli* and *Streptococcus faecalis*; sensitization of the colon to foreign protein of food and bacterial origin, and secondary or conditioned deficiency disease. Successful medical treatment is based on the evaluation and control of these factors. Prognosis depends in part on this and in part on the degree of permanent damage to the colon. Radical surgery should be seriously considered in those cases which fail to respond to conservative treatment, in those which exhibit the effects of chronic sepsis, and early in those which present the proximal type of pathologic change.

CONCLUSIONS

1. Chronic ulcerative colitis appears to be the complex expression of the interaction of several different factors.
2. The disease exhibits an inherent tendency to progression and relapse.
3. Although the prognosis under medical management is good in the pathologically mild and moderately advanced case, the term 'apparently arrested' should be substituted for 'cured'.
4. Prolonged joint medical and surgical observation is essential for the pathologically advanced case.
5. Combined medical and radical surgical treatment offers the best prognosis for many of the pathologically advanced cases.

Vitamin Therapy in Ophthalmic Practice

By JOSEPH LAVAL, M.D.

(From the *American Journal of Ophthalmology*, Vol. XXII, January 1939, p. 33)

Much has been written about the importance of vitamins in general medicine, and three reviews have appeared in ophthalmic literature. It must of course be realized that much of what follows will be only suggestive and show certain trends and indications as to the uses of the various vitamins in ophthalmic practice. Definitely positive statements and findings will be infrequent, but some general conclusions will be self-evident.

VITAMIN A

This vitamin is best associated in our minds with cod-liver oil and recently with haliver oil. It is present in good amounts in eggs, butter, milk, cream, and such dairy products. A deficiency of this vitamin manifests itself clinically first, as night blindness (hemeralopia) and later as xerophthalmia. Recently, dark-adaptation tests in early and beginning A avitaminosis have been advocated, but as yet they are not sufficiently standardized to warrant positive statements. It has been shown that the visual purple of the retina after exposure to strong sunlight regenerates slowly in the eyes of rats on a diet deficient in vitamin A and it has also been proved that the normal retina is rich in vitamin A. Vitamin A has been used to cure xerophthalmia and the hemeralopia due to depletion of vitamin A with, of course, brilliant results, as witness the cases of the fishermen of Labrador as reported by Aykroyd, and the cases of the natives of the Philippine Islands reported by Gamboa. However, vitamin A has been used for the hemeralopia due to retinitis pigmentosa with no improvement at all, as was reported by me in 1933.

Vitamin A is being used also in the conjunctival sac with massage into the cornea in cases of keratitis dystrophica, but the results are variable. Some authors report brilliant results, others no improvement. In the

writer's own experience there were some cases in which it seemed to do much good, others in which irritation and aggravation of the symptoms resulted.

In certain cases of blepharitis and conjunctivitis in children there is no doubt that malnutrition is a factor and here large doses of cod-liver oil are beneficial. Pillat reports the changes in Chinese eyes as a result of vitamin-A deficiency and mentions night blindness, dryness of the conjunctiva, Bitot's spots, xerosis, and even keratomalacia, meibomitis, hordeolum, and blepharitis. Vitamin A is also of use in phlyctenular kerato-conjunctivitis and other related conditions of scrofulous origin. In women a low-grade chronic conjunctivitis with mild photophobia may be due to A avitaminosis as a result of dieting in the effort to keep a streamlined figure. Langdom described the case of a young woman who used no butter, eggs, or milk and had a corneal dystrophy which cleared up on the administration of cod-liver oil.

When depletion of vitamin A is advanced, changes in the lacrimal gland result with diminution and even entire loss of lacrimation. Mori showed that these changes in the lacrimal gland were responsible for conjunctival changes in xerophthalmia, which then gave rise to the corneal changes. Yudkin, in similar experiments, drew different conclusions as to which lesions arose first, but Wolbach and Howe demonstrated that all the changes are due to a replacement of the columnar epithelium by stratified squamous epithelium going on to keratinization.

In diabetics there may be an increased demand for vitamin A, as certain experiments by Ralli *et al.* showed. In depancreatized dogs (artificial diabetes) it was found that definite corneal epithelial changes occurred of the same type as in vitamin-A deficiency. These corneal changes were prevented by feeding cod-liver oil to the depancreatized dogs. Apparently, in these diabetic animals the demand for vitamin A is increased.

VITAMIN B

This vitamin is found in such foods as meats, potatoes, and green vegetables, but is most concentrated in yeast. It has various complex components the most important of which are B₁, the antiberi-beri component (thiamine) and B₂ or G, the antipellagra portion (riboflavin), the absence of the latter causing cataracts in rats. However, for clinical purposes it is to be remembered that concentrated yeast tablets as marketed by any of the reliable pharmaceutical firms contain B₁ and B₂ in high amounts.

In the Archives of Ophthalmology for December 1934, the writer reported a case of bilateral acute optic neuritis with marked diminution of vision associated with pellagra. (It is known that the peripheral neuritis of pellagra and of beri-beri is due to the lack of vitamin B₂ and B₁, respectively.) In this case the pellagra and optic neuritis both were cured, even though alcohol was taken in fairly large amounts daily, because yeast was administered in large doses, thus supplying the necessary quantity of vitamin B₂. In a case of toxic amblyopia due to alcohol, recently observed, vision was improved from hand movements to 20/20 for each eye in a period of two weeks by administering vitamin B₁ and B₂ in the form of yeast tablets, even though some alcohol was taken daily. Carroll reported the same results in a series of cases in 1937, and the present writer quoted Shastid's experience with cases of optic neuritis cured by vitamin B₁ and B₂. In all cases of retrobulbar neuritis, toxic amblyopia, and optic neuritis—whether due to nasal sinus infection, alcohol and tobacco, or multiple sclerosis—it would seem advisable to use concentrated yeast tablets to supply large amounts of vitamin B₁ and B₂.

Similarly, in cases of incipient cataract the same therapy should be carried out, for riboflavin (anti-cataractous for rats) is present in the concentrated yeast tablets. Furthermore, there is sulphur in these yeast tablets (HS-cystine), and some connection between the sulphur content of fish lenses and the

prevention of human cataracts has been reported by Shropshire. A further connection between cystine and the formation of galactose cataracts in rats has also been shown; this will be discussed under vitamin C.

VITAMIN C

This vitamin is found in the citrus fruits—orange, grapefruit, lemon, and lime. The pure crystal in the form of ascorbic acid has been prepared.

According to Bellows and Rosner, 'In normal eyes the lens and aqueous are rich in vitamin C, in the cataractous lens the amount of vitamin C is diminished or entirely absent, and the aqueous of an aphakic eye contains only a slight amount of this substance. Experiments were performed which showed a definite reduction in the vitamin-C content of the blood in persons with cataract. Furthermore, vitamin C is absorbed from the conjunctival sac into the anterior chamber. Presumably this takes place through the cornea'. These investigators also proved that the substance in the lens which reduces a special dye (sodium 2, 6, di-chlorobenzenone-indophenol) is entirely vitamin C, and not any other reducing substances such as sulphhydryls. Bellows went still further and showed that the cataract produced in the albino rat by lactose and by galactose is due to a loss of the sulphhydryl content of the crystalline lens which can be delayed by cystine and to a lesser degree by vitamin C in this type of cataract. Accordingly, it would seem that in cases of incipient cataract vitamin B₁ and vitamin B₂, to supply the cystine, and also vitamin C should be administered. In the writer's own practice this procedure has been carried out for the past four years, but of course no conclusions should be drawn as yet.

Bietti believes that the decrease in the amount of vitamin C in the aqueous and in the cataractous lens is the result of the lens changes and not the cause. He was unable to prevent or influence naphthalene cataract by administering vitamin C.

In 1932 Szent-Györgyi and Svirbely in Hungary proved that hexuronic acid is vitamin C. At the same time King and Waugh of the University of Pittsburgh showed that a crystalline compound which they isolated from lemon juice was identical with hexuronic acid. Szent-Györgyi found that the best source of vitamin C was the peppers grown in Hungary. However, patients with purpura were relieved by the juice of peppers of citrus fruits but not by the pure crystalline vitamin C. On further investigation it was found that citrus fruits and the peppers contain a second substance controlling the permeability of capillaries and this substance is called vitamin P. The symptoms of scurvy seem to be due to a lack of both vitamin C and P.

Accordingly, it would seem advisable for ophthalmologists to utilize the juice of citrus fruits in large doses in attempting to control intra-ocular hæmorrhage whether due to trauma (operative or other) or to some metabolic disease such as diabetes. Yudkin recently advocated the same therapy and seemed quite encouraged by its results. The present writer has also tried it in several cases of intra-ocular hæmorrhage, both postoperative and metabolic, and feels encouraged enough to continue with its use.

VITAMIN D

The use of vitamin D in ophthalmology has been limited to cases of myopia in the hope that this vitamin plus calcium would cause an increase in the amount of calcium in the sclera and thus prevent further stretching. Recently the writer reviewed this subject and gave the results of clinical experiments which showed no favourable influence on myopia after vitamin-D therapy. However, it should be borne in mind that the prescribed dosage of 10 minims daily may have been insufficient. Inasmuch, however, as this is the dosage for cases of rickets we may assume that it is sufficient for cases of myopia investigated clinically. The use of vitamin D in keratoconus has also been suggested.

SUMMARY

It is suggested that in cases of the following vitamin deficiencies it might be theoretically valuable to prescribe the following treatment:—

1. Vitamin A—Prescribe a tablespoonful twice daily in cases of poor dark adaptation, phlyctenular keratoconjunctivitis, photophobia, and low-grade conjunctivitis in women who are on a slenderizing diet or in cases of other corneal and conjunctival lesions in which the history shows a lack of vitamin A intake.

2. Vitamin B (B_1 and B_2)—Prescribe eight yeast tablets daily of the brewer's-yeast type put up by any of the reliable pharmaceutical firms, or the powdered form may be ordered. This is to be used in cases of incipient cataract, in optic neuritis, retrobulbar neuritis, and also in toxic amblyopia.

3. Vitamin C—Order the juice of at least two large oranges or one grapefruit daily in cases of incipient cataract. (This is plus the brewer's yeast which is also to be taken daily.) In cases of intra-ocular hæmorrhage order the juice of four lemons daily.

Reviews

THE NATURAL HISTORY OF POPULATION.—By Raymond Pearl. 1939. Oxford University Press, London, Humphrey Milford. Pp. xii plus 416. Illustrated. Price, 10s. 6d. Obtainable from Oxford University Press, Bombay and Calcutta

THE problem of human fertility has always aroused keen discussion among students of population movements. Half a century ago the Malthusian doctrine of over population prevailed and birth control propaganda was a prominent feature of practical population policy for social amelioration. To-day the world—at least the civilized western population—is faced with fear of deterioration. The fertility of higher social classes is declining. The causes of this differential fertility are, however, not clearly known. It is, therefore, of great interest and value that Professor Pearl has compiled in this book the results of his researches on differential fertility which he has been carrying out for some years past. The material on which his studies have been based throws new light on the reproductive activity of the western population, in particular that of the United States of America.

A brief exposition of his views on the basic biological factors which control the history of population is clearly set out in the opening chapter. An attempt has been made to study the influence of such complex factors as environment, instinct, emotion and intelligence on both the quantitative as well as qualitative aspects of population. Evidence is presented to show that the differential fertility which exists between the whites and the negroes is not innate but can be traced primarily to environmental (non-genetic) influences and particularly to the variation in the prevalence and effectiveness of contraceptive practices.

From a brief consideration of the general biological factors he passes on, in the second chapter, to a detailed discussion of the biology of human fertility. The overt fertility in human beings, as distinguished from innate fertility, is the resultant of the play of a large number of complex factors. Some of the important factors considered in detail are the sexual desire (libido), age, span of reproductive life in female as well as in male, litter size, frequency of coitus, prevalence and effectiveness of contraceptive efforts and reproductive wastage due to abortion, miscarriage and stillbirth. In a concise form the author has presented a volume of material compiled from a variety of sources. A new conception in the study of age variation in fertility has been introduced. Thus in the case of a woman who remains overtly fertile throughout the reproductive period he has studied the manner in which the intensity of fertility would vary with age. He has shown, from data specially collected for this purpose, that the changes in fertility with respect to age are, in certain respects, quite different in the case of a woman who remains fertile as compared with the age specific fertility rates for groups of population. The latter includes a group as large as 56 per cent of women who were previously fertile but became sterile after the age of 28 years. In this chapter he also gives the latest estimates of the safe period, of the mean ages at menarche and at menopause, and tries to appraise the

significance of the effects of such factors, as climatic, social, economic and secular or the human reproductive pattern. For the first time, perhaps, are presented statistical data bearing on the quantitative aspect of the human sex behaviour of American couples. The author has shown that 253 out of each 254 copulations, on the average, which might have been effective were actually unproductive even though no attempts were made at any form of contraception. Some of the results emerging out of his investigations on the copulatory activity of American couples are not only interesting but astonishing. The reproductive wastage in legitimate pregnancies is around 200 per thousand pregnancies. A new statistical index devised by the author, which he has termed 'pregnancy rate' has been described. This according to the author 'measures one aspect of fertility with a higher degree of statistical specificity relative to the biological processes of human reproduction than any other hitherto used'. This concept of pregnancy rates specified for age and colour has been used later on in the book for the study of various problems arising out of differential fertility.

The author has attempted to assess in statistical terms how the human reproductive pattern, particularly of the United States, differs from that of animals lower in the evolutionary scale. Data have been presented in regard to infra-human reproductive capacity. With regard to secular change he believes that, under the present social and environmental conditions, there appears to be a definite trend towards less and less human reproduction, probably without any great lessening of human sexual activity. Thus his statistical studies reveal that only about 10 per cent of the women in the United States who were physiologically potentially capable of reproduction actually reproduced in the year 1930 and that this proportion was definitely smaller for all the age groups of mothers in 1930 than it was in 1920, and this change could not be wholly attributed to an increase in contraceptive efforts in the ten-year period. He has discussed this fertility decline in regard to colour and has shown that a greater decline has been experienced in negro population as compared with the native white and concludes that 'the main burden must surely be placed somewhere else than upon birth control so far as concerns the negroes'.

With the co-operation of the qualified medical staff in the obstetric service of several hospitals in the United States he collected a comprehensive account of the entire reproductive histories of about 31 thousand normal women together with a detailed account of their use of contraceptives. Information was also obtained about other relevant circumstances of their lives, e.g., educational, social, economic, health and religious status. This material afforded a fairly representative sample of the general population and particularly of the urban population of the United States. The frequency of use and prevalence of contraceptive practices and their effectiveness is statistically appraised for population groups differing widely not only in social, educational and racial characteristics, but varying also in age, religious affiliations

and occupations. The author finds that 'if it were not for the effect of contraceptive efforts and the practice of criminal abortion together with correlated habits as to postponement of marriage, there would apparently be little or no significant differential fertility as between the economic, educational, and religious classes of urban American married couples'. One consistent broad result that emerges is that the steady decline in total fertility that has gone on in the past and is even now continuing, not only in the differentiated classes but in the population as a whole, cannot be attributed solely or even primarily to the causes producing differential fertility. Some other obscure factors are involved and for their investigation he devotes the last chapter to a discussion of the population history of the world. He finds that fertility decline although historically of recent appearance is 'a world-embracing phenomena—something affecting man as a species' and is not confined exclusively to the highly civilized countries. Prior to this decline the world population showed within the period 1630 to 1930 a short spurt of population growth resulting in a fivefold increase. This, according to the author, happened because of simultaneous advance in scientific discovery and the application of its results to man's basic requirement, i.e., the exploitation of his natural environment. The consequence of this increase has been an entirely disproportionate increase in population density and his investigations throw light on the various socio-economic questions consequent thereupon. Although the trend of the arguments advanced appears speculative, the chapter provides a dispassionate discussion of the world population problem from social, economic and political standpoints.

The book is well illustrated and for preserving continuity of discussion most of the tables have been set in the appendix. The notes relegated towards the end of the book provide valuable information as well as interesting reading. The bibliography runs to about 700 titles and index adds to the value of the publication.

The great merit of the book, however, is that it provides a masterly exposition and analysis of a unique type of statistical data bearing upon the problems connected with the biology of human reproduction and differential fertility.

S. S.

THE BRITISH ENCYCLOPÆDIA OF MEDICAL PRACTICE: INCLUDING MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY AND OTHER SPECIAL SUBJECTS.—Under the General Editorship of Sir H. Rolleston, Bt., G.C.V.O., K.C.B., M.D., D.Sc., D.C.L., LL.D. Butterworth and Company, Limited, London. (To be completed in 12 volumes.) Sold in complete sets only. Cash price, Rs. 25 per volume. Also available on the instalment system at Rs. 10 per month. Price, Rs. 26-8 per volume. Only available from Messrs. Butterworth and Company (India), Limited, Calcutta. Volume X. Pp. xxiii plus 688 plus 43

THE tenth volume covers subjects from poisons to rosacea. The first chapter deals with legislation in Great Britain on poisons. With the numerous schedules under which poisonous drugs are classed, the subject has become a very complex one, and the chapter will be very welcome to practitioners in this country who are likely to visit England; even if they do not intend to practise there, they will find the information useful when they want to prescribe for themselves or their families. As the near future must bring forth central and provincial legislation on poisonous drugs, we can commend this chapter to those who will help to frame such legislation.

The two most important subjects in this volume are pregnancy and psychology. The former subject is dealt with in a single chapter of 75 pages by Professor F. J. Brown of University College Hospital. Both normal and abnormal pregnancies are considered. A later chapter in this volume is on the puerperium. These two chapters combined with the excellent chapter

on labour in volume 7 make a very complete textbook on obstetrics.

The 160 pages on psychology are divided up into a number of chapters which are contributed by nine writers, psychiatry in children, psycho-analysis, psychoneuroses and psycho-therapy, psychopathic personality, and finally psychoses. The psychoses are dealt with under seven headings. There is a sub-section on neurasthenia in the tropics in which Dr. P. Manson-Bahr has given a very well-balanced and useful account of this condition. Schizophrenia is one of the few psychoses in which active treatment is undertaken with any hope of success; both the insulin and cardiazol-convulsion treatments are described.

Of tropical diseases rat-bite fever by Dr. B. M. Das Gupta and the relapsing fevers by Sir John Megaw come in this volume. Full and clear accounts of these diseases are given. Dr. B. M. Das Gupta dismisses *Actinomyces muris* (*Streptothrix*) as a contaminant and confines his remarks to *Spirillum minus* infection. It is possible that the former also produces a similar clinical syndrome in other countries. Sir John takes a view that he has always championed, and which is now generally accepted, that louse relapsing and tick relapsing fever should be considered as separate diseases, in view of the differences in the epidemiology, the aetiology, and the clinical manifestations.

A good account of the aetiology and treatment of prickly heat is given by a non-tropical worker, Dr. Sidney Thomson of King's College Hospital. The physician in the tropics, who has at some time suffered from this always annoying and occasionally serious condition, is liable to be prejudiced in his opinions on its treatment by his own personal experience; a treatment that will prevent or cure the condition in one person will often have no effect on another, so that this unprejudiced and well-balanced review of the treatments advocated by different observers is welcome.

Printers are guided by strict rules and it is difficult to get them to depart from these, even when the exigencies of the occasion demand; one such rule is that, when a text-figure occupies half a column, it must be placed on the outside half, that is, on the right on the odd pages and on the left on the even. Page 153 of this volume, where three marginal 'captions' happen to coincide with three important structures in a text-figure, provides an example where departure from this rule would have prevented at least one reader from doubting his own mental balance for one brief moment.

It is perhaps significant that this querulous criticism is the only one that the reviewer is able to make.

TREATMENT IN GENERAL PRACTICE. VOLUME III. ANÆSTHESIA: SURGERY. (Articles republished from the 'British Medical Journal'.) 1939. H. K. Lewis and Company, Limited, London. Pp. xi plus 402, with 60 illustrations. Price, 10s. 6d.

THE two earlier volumes of this series have been deservedly popular, so much so that the publishers considered it advisable to publish second editions of both—an unusual procedure with a publication of this kind. The third volume should prove equally popular. The earlier volumes dealt mainly with medical treatment and the present volume forms a useful complement, in that it deals with anæsthesia and minor surgery.

There are sixteen chapters on different aspects of treatment; the first five are general ones on such subjects as the choice of an anæsthetic in general practice, stages and signs of general anæsthesia, and the depth of anæsthesia for various operations, the last two being written by Dr. Langton Hewer of St. Bartholomew's Hospital. The next six are on special types of anæsthesia or anæsthesia for special occasions, e.g., basal anæsthesia for short operations, local anæsthesia, anæsthesia for dentistry and anæsthesia in midwifery. The last five chapters are again on more general subjects. The chapter on premedication is a useful one; this is perhaps the most humanitarian of recent, or comparatively recent, refinements in medical

practice, the obliteration from the patient's consciousness of the terrifying journey to the operating theatre, the often long delay in the ante-room, and the unpleasant commencement of anaesthesia.

There are twenty-seven articles on minor surgical procedures. The figures given for the treatment of burns and scalds at St. Thomas's Hospital in different periods during the last fifty years are very impressive. The mortality rate for burns has been reduced from nearly 40 per cent to 4 per cent; this last figure is of course since the introduction of tannic acid. One could almost say that it amounted to malpraxis to treat burns and scalds in any other way.

The articles all appear to be well written and in each case the subject is dealt with from a practical point of view.

CARDIOVASCULAR DISEASE IN GENERAL PRACTICE.—By T. East, M.A., D.M. (Oxon.), F.R.C.P. (Lond.). 1938. H. K. Lewis and Company, Limited, London. Pp. x plus 206, with 43 illustrations. Price, 10s. 6d.

This is the book on cardiology that we have been looking for for a long time. It is all very well for the physician who has taken out a special course and worked with the leading cardiologists in Great Britain to come back here and teach the student that percussion of the heart is liable to lead one into gross errors and that an orthodiagram should be done in every case, but the fact remains that on ninety-nine occasions out of a hundred his students, when they start practice, will have to depend on their fingers and ears for ascertaining the size of their patients' hearts, and that in India only one in every thousand or so persons dying of coronary disease dies with comfort of the electrocardiogram. We do not mean to suggest that radiography and electrocardiography are not useful procedures and we fully appreciate the fact that much of our recently-acquired knowledge on cardiology has been obtained through these ingenious devices. There is not in this volume a single electrocardiogram, but there are many cardiac outlines, which, as the author says, help one to cultivate the x-ray eye.

It is not necessary to discuss this book in detail. Modern knowledge and modern teaching in cardiology are presented to the reader clearly and concisely, and in such a way that he ought to be able to tackle a case of heart disease without any feeling of the handicap that the absence of the elaborate instruments, available only in large hospitals, might engender. The student will find that the most elementary details are included; these will help him to obtain a proper grounding in this important subject, but it is to the general practitioner in India that we can recommend this book most warmly.

THE PNEUMONIAS.—By H. A. Reimann, M.D. 1938. W. B. Saunders Company, Philadelphia and London. Pp. 381, with 111 illustrations. Price, 25s.

THERE is at the present moment every indication that in the future the history of the treatment of pneumonia will be divided into three periods—the pre-serum period, the serum period, and the M & B 693 period. One of course expects that other sulphanilamide compounds will be found that are even more efficacious, but the improvement in the mortality figures that has been effected by the introduction of M & B 693 far exceeds that which followed the introduction of specific anti-sera. This book which comes from America bears a date of only six months ago, but the references to sulphanilamide include the statement that this group of drugs plays no part in the treatment of pneumonia, though there is also a hopeful note, referring to recent animal experiments, which suggests that the future may see the introduction of some member of this group, efficacious in pneumonia. Medical science moves so fast in these days that the print recording the last discovery has scarcely sufficient time to dry before it is out of date.

Nevertheless, this volume is one of the best monographs on pneumonia so far published, and anyone who purchases it will have no difficulty in grafting new

knowledge on the treatment and prognosis of this disease on to the sound pathological, bacteriological, biochemical, symptomatological, and radiological groundwork that is conveyed in this book.

We can strongly recommend this book to those interested either in chest disease in general or in pneumonia in particular.

INTERNAL MEDICINE: ITS THEORY AND PRACTICE.—In Contributions by American Authors. Edited by J. H. Musser, B.S., M.D., F.A.C.P. Third Edition. 1938. Henry Kimpton, London. Pp. 1428. Illustrated. Price, 45s.

THE object of the eminent American contributors of this book is to bring out the important features of medicine, so that the reader may understand the basic facts of disease. No attempt has been made to make the book a comprehensive encyclopædia of the subject—a task impossible in a one-volume work.

The book is divided into four parts; part I deals with infectious diseases, part II, systemic diseases, part III, diseases of nutrition, allergy, metabolism, physical and chemical agents, and part IV, diseases of the nervous system. The last includes the mental diseases in addition to the organic diseases of the nervous system.

Each disease has been dealt with under the usual headings, viz, definition, history, incidence, aetiology, pathology, symptomatology, diagnosis, differential diagnosis, prognosis and treatment. Each heading contains a concise exposition of the modern conception of the subject, and the outstanding features of the various diseases have been well described.

General practitioners would have welcomed more detailed description of at least some of the commoner diseases; e.g., no mention is made of the 'atypical' varieties (apical, central, massive and other varieties) of lobar pneumonia. The description of clinical features and treatment of blackwater fever is meagre and inadequate. The authors have in some instances described treatment in its barest outline, without going into details, e.g., in the treatment of streptococcal infection mention only is made of sulphaurilamide compounds and no details as to their dosage, or dangers and precautions in their use have been given. There is no mention of chrysotherapy in the treatment of pulmonary tuberculosis. In the treatment of kala-azar, the author has only mentioned neostibosan and urea stibamine as useful preparations, but no details of dosage or course of treatment with these have been given, though he has written elaborately on sodium and potassium antimony tartrate, the drugs that are becoming obsolete in the treatment of this disease. The chapter on diseases of the blood should contain a section on tropical macrocytic anaemia, and a modern classification of anemias.

The undergraduate medical student will however find this book valuable. He will learn the important features of the various diseased states including the pathologic physiology and the mechanism of production of symptoms and signs. Understanding of these fundamentals will make the comprehension of medicine relatively easier to him.

The get-up, printing and illustrations are excellent, and bear testimony to the high standard maintained by the publishers.

P. C. S. G.

THE PHYSIOLOGY OF ANÆSTHESIA.—By Henry K. Beecher, A.B., A.M., M.D. 1938. Oxford University Press, London, New York, Toronto. Pp. xiv plus 388. Price, 17s. 6d. Obtainable from Oxford University Press, Bombay and Calcutta

The book under review deals chiefly with the theoretical aspects of anaesthesia.

It is an attempt on the part of the author to interpret the various clinical manifestations and other systemic reactions during anaesthesia with almost all the known anaesthetic agents, and to correlate them as far as possible with experimental findings.

In his endeavour to do so almost all the material available up to date has been collected and placed at

the disposal of the reader. To realize the vast amount of literature that has been consulted one has only to glance over the forty-five pages of useful and well arranged bibliography at the end of the book.

The use of rectal avertin or barbiturates has been rightly condemned because of the 'fact that the lethal dose of these agents is worryingly near the clinical dose'. Because of the 'harmful cardiac effects similar to those of chloroform' general anaesthesia with ethyl-chloride has also been deprecated.

In a work which deals so exhaustively with the pharmacological aspects of practically all the drugs used as anaesthetics and pre-anaesthetics, pentothal receives scant attention and scopolamine and paraldehyde—two widely used agents in premedication—find no place.

The author's apology in writing this book is mainly to supply a reference work particularly for those who want 'to explore the controversial fields of anaesthesia'. Looked at from that standpoint the book is certainly a good one and of great help to a research worker.

M. C. G.

MODERN SURGICAL TECHNIQUE.—By M. Thorok, M.D., K.L.H. (France), K.C. (Italy). 1938. Published by J. B. Lippincott Company, Philadelphia and London. Volume I:—General Operative Consideration, Surgery of the Head and Neck and Plastic Surgery. Pp. xiii plus 526 plus xix. Volume II:—Surgery of Nerves, Vessels, Bones, Surgery of Breast and Chest. Pp. vii plus from 527 to 1229 plus xxv. Volume III:—Abdominal Surgery, Hernia, Genito-Urinary and Gynaecologic Surgery. Pp. viii plus from 1230 to 2045 plus xxix. Complete in three volumes with 2,174 illustrations. Price, £7-10 per set of three volumes. Not sold separately. Obtainable from Messrs. Butterworth and Company (India), Limited, Calcutta. Price, Rs. 100

This important new treatise on operative surgery successfully achieves a dual purpose; it describes in detail not only the common operations of surgery, but also the technique of many new methods. The author also carries out the promise made in the preface to describe the 'classical' operations of surgery, a lead that more than one standard textbook of operative surgery would do well to follow.

The first volume opens with chapters which discuss broadly the patient before and after operation, surgical equipment, and anaesthesia. The figures illustrating the section on regional anaesthesia are specially noteworthy. The second part of this volume is devoted to the surgery of the head and neck, much space being given to new work on the skull and brain, especially the work of Krause.

Orthopaedic surgery occupies much of volume II. In the section on tendon transplantation operations on the lower limb are minutely described, but no space is given to operations about the wrist. This is a pity because, owing to the use that can be made of the synergic action of the flexors and extensors of the wrist, better functional results can be obtained in this joint than in the joints of the lower limb.

It is disappointing to find no mention of the use of the Smith Petersen pin in the treatment of fractures of the femoral neck, a procedure that has found world-wide acceptance.

The work of Lorenz Böhler has won even more important recognition, but his methods receive no attention in this book.

The section on the surgery of the thorax is full of much new work and makes most interesting reading. In this part will be found a reproduction of Meyer's illustrated description of pulmonary embolectomy with which every surgeon should be acquainted.

Volume III describes abdominal and genito-urinary surgery, an operation of special interest being the author's method of electro-surgical obliteration of the gall-bladder.

The book, though over two thousand pages in length, is easy to read, a feature being the printing of

important passages in heavy type. Moreover errata are almost absent, although in future editions we hope to see corrected the passage that states that the thyroid gland receives its blood supply from the 'superior thyroid, middle thyroid, and inferior thyroid'. (Vol. I, p. 437.) Also, surely figures 2085 and 2108 have been accidentally turned on their sides?

Certain gems of 'neo-grammar' appear, such as 'skeletonize', 'extra-peritonealization', 'ascitization', and 'cholecystelectrocoagulectomy'. It is no use; we shall have to submit to this eventually but we shall go down fighting.

Though modestly described as succinct by its author, this is undoubtedly a major work, and destined to take an important place beside the other comprehensive textbooks on surgical technique.

W. McN. N.

DISEASES OF THE CHEST AND THE PRINCIPLES OF PHYSICAL DIAGNOSIS.—By George W. Norris, A.B., M.D., and H. R. M. Landis, A.M., M.D., Sc.D. Sixth Edition. 1938. W. B. Saunders Company, Philadelphia and London. Pp. 1019, with 474 illustrations. Price, 45s.

This volume of 1019 pages, with 474 illustrations, has been written by two former professors of clinical medicine in the University of Pennsylvania, special sections on diseases of the bronchi, lungs, pleura and diaphragm, transmission of sounds through the chest and electro-cardiography and the cardiac arrhythmias, including x-ray study of the heart and great vessels being contributed by specialists in the respective subjects. It is unfortunate that one of the authors (Dr. Landis) died before the present edition could be put through the press. The book is dedicated to the authors' mutual friend, Dr. Fetterolf, who was responsible for the many frozen sections of organs with illustrations of which the book is adorned.

Many will agree with the authors in the view that with the increasing use of laboratory methods, which are frequently necessary and sometimes essential to accurate diagnosis, the importance of the clinical methods of the diagnosis of heart and lungs in health and disease is being neglected. To explain and emphasize these methods in their proper perspective with the help of up-to-date knowledge at our disposal, the authors have published this treatise for the use of senior medical students and doctors. And we must say that they have succeeded in their effort.

The book is divided into four parts. Part I deals with the examination of the lungs and the interpretation of normal sounds and their variation from the same. The chapter on the transmission of sounds through the chest is specially interesting. The normal variations of percussion and auscultation sounds have received special attention. We are, however, sorry to notice that the usefulness of radiology in the diagnosis of pulmonary conditions has not received as much attention as it deserves, not even in the investigation of the diseases of children. This has been rectified in the case of the circulatory system dealt with in part II, which deals with the examination of the circulatory system, including electro-cardiography and x-ray study. Vital capacity, functional tests, basal metabolism, the effort syndrome and other additional methods have been described. Part III deals with diseases of the bronchi, lungs, pleura and diaphragm. Part IV deals with diseases of the heart, including the pericardium, coronary arteries, and thoracic aorta.

The present edition has been thoroughly revised and brought up to date, the portions dealing with bronchial asthma, bronchiectasis, lung abscess and cystic disease and the relations of nasal and accessory sinus disease to infections of the lower air tract being completely re-written.

We commend the book particularly to teachers of medicine. The reproductions of frozen sections, photographs and diagrams leave nothing to be desired. The printing and get-up reflect credit on the publishers.

A. C. U.

YAWS. (FRAMBOESIA TROPICA).—By H. D. Chambers, M.B., Ch.B. (Aberd.). 1938. J. and A. Churchill Limited, London. Pp. xiv plus 169. Price, 5s.

THE author makes a bad start, for the naïveties of his preface must fill the average reader with misgivings. This preface contains the following surprising and totally irrelevant paragraph:—

'Gonorrhoea is prevalent because so few heed the teachings of the Church regarding marriage. Perhaps, some day, stringent legislation against illegitimacy will effect a diminution in the incidence of the disease. Such legislation would also be a step towards rescuing from malnutrition and disease many children born out of wedlock'.

Then, when he does get to the subject of the book he makes this penetrating observation on the epidemiology.

'The disease is confined to the damp areas of the island where living conditions are unhygienic. In parts of the island where conditions are not conducive to the disease yaws is almost unknown'. He concludes his preface by mentioning that the book is written for members of parochial boards and ministers of religion, amongst others, of course.

The book itself does however do something to dispel, or shall we say mitigate, this bad impression. The historical descriptions are interesting and there are many details not found in ordinary textbooks. The reference in the foreword to the book being 'eminently readable' cannot however be upheld as never has any book caused the reviewer's editorial pencil to itch so continuously.

The writer's sense of uniformity is entirely undeveloped. On p. 37 the causative organism is given as *Spirochæta pertenuis*, on the next page as *Spirochæta pertennis*. A few lines further down we are back to *Spirochæta pertenuis* (yaws germs); on p. 41 it is again *Spirochæta pertennis* (yaws germs) and on p. 42, it is again *Spirochæta pertenuis*. Strict alternation seems to have been observed. On p. 1 it is *Treponema pertenuis*, on p. 21 *Treponema pertenuis*, and on p. 76 *Treponema pertennis*.

His grammar is usually correct but some of his sentences just haven't any meaning. 'These three places, however, have a very heavy rainfall, and by reason of their proximity to the sea do not fall in any season much below their mean annual temperature' as a sentence doesn't make sense nor is it correct in fact or implication, and 'The Wassermann reaction test of blood withdrawn from the arm in patients with yaws lesions begins to give positive results around the third and fourth week after infection with *Spirochæta pertennis*'.

The author's strong point is not either geography or climatology. He has an *idée fixe* regarding high temperature, humidity and yaws endemicity, and if geographical facts don't fit in with this, well, they just have to be altered.

He refers to the North-West Frontier Province on being 'more or less' on the same latitude as Burma. 'More or less' is a wide term, but Peshawar is as many degrees north of the central point of Burma, as the Arctic circle is north of Manchester, and he places Lower Chindwin in Assam.

Technical expressions are used freely, often too freely we should imagine for the composure of some members of parochial boards, and the parenthetical explanations are not always very helpful, e.g., 'Wassermann reaction (blood test)', varied by '(blood test result)' and on the same subject 'The titre (indication of impurity)'; this is presumably for the benefit of ministers of religion.

The author has had such exceptional experience and there is so much good in this book that the reviewer would recommend him, first to make up his mind whether he wants to write a popular book or a serious contribution to medical science, and then, whichever course he has decided upon, to sit down and rewrite the whole book.

L. E. N.

THE PRACTICE OF REFRACTION.—By Sir Stewart Duke-Elder, M.A., D.Sc. (St. And.), Ph.D. (Lond.), M.D., Ch.B., F.R.C.S. Third Edition. 1938. J. and A. Churchill, Limited, London. Pp. xv plus 371, with 183 illustrations. Price, 12s. 6d.

THIS is the third edition of this book and retains the essential character of preceding editions in that it aims to be a simple clinical guide for the student and the practitioner in the prescribing of spectacles, without hindering him with innumerable mathematical proofs.

The book consists of 371 pages divided into six sections. The first section deals with eye-strain, the second with the principles of refraction, the refraction of the eye, the anomalies of refraction and the changes in refraction; the third section deals with accommodation, convergence, presbyopia and the anomalies of accommodation. Section four deals with orthophoria, heterophoria and heterotropia. Section five deals with the general outline of ophthalmological examination, the visual acuity, ophthalmoscopic examination, retinoscopy and the subjective verification of the refraction and the testing of the muscular equilibrium. Section six deals with the making and fitting of spectacles.

Finally there are six appendices which deal with the refractive indices, a table showing the equivalents of centradis in prism dioptres, in degrees of deviation and in degrees of refracting angle, metre angles, lenses of the same effectivity for near and for distant work, the formulae for periscope lenses and the official visual requirements.

The author very wisely points out the art of refraction cannot in any sense be learned by reading a textbook and that the only way of attaining efficiency is by constant and careful work in the refraction department of an eye hospital where large numbers of cases of all kinds are available and where the findings of the young refractionist can be supervised.

In the new edition some new matter has been added, dealing particularly with such problems as aniseikonia, muscular imbalance, dynamic retinoscopy, orthoptic exercises, contact glasses and so on.

The book is well illustrated and written in a clear simple style. We recommend it to all medical men interested in ophthalmology as a most useful book for their library.

E. O'G. K.

SHOCK AND RELATED CAPILLARY PHENOMENA.—By V. H. Moon, A.B., M.Sc., M.D. 1938. Oxford University Press, London. Pp. xviii plus 442. Illustrated. Price, 21s. Obtainable from Oxford University Press, Bombay and Calcutta

THE elusive problem of the phenomena of shock has a fascination of its own. In a foreword, Dr. W. B. Cannon commends the new aspect of Dr. Moon's explanation which embodies a comparison with pathological processes obtained, for example, in cholera, certain toxæmias and infections. This monograph may, therefore, be regarded as a complete survey of recorded studies on shock; it has the added advantage of having been investigated from the pathological standpoint.

There are twenty-three chapters in this book and an appendix containing practical considerations. The first four chapters deal with the minute anatomy, reactions and permeability of capillaries and give a clear explanation of dilatory actions, formation of lymph and the triple response. The view of Lewis is quoted that 'whenever the skin displays an acute reaction in the form of the triple response this reaction is provoked by H-substance'... a single substance believed to be closely related to histamine. In the subsequent chapters there is a careful consideration of the theories concerning shock, 'locus minoris resistentiæ' and traumatic toxæmia. Shock has been defined as a 'circulatory deficiency, neither cardiac nor vaso-motor in origin, characterized by decreased blood volume, decreased cardiac output (reduced volume flow) and by increased concentration of the blood'. The diverse

conditions under which shock may be expected to occur, and the contributory factors, have been carefully analysed. The analogy of cholera is of particular interest to us in this country. Probably no disease results in circulatory collapse more quickly than is seen in severe cases of cholera. Crowell's experience of 92 post-mortem examinations in the Philippine Islands is worthy of note. He described many of the features characteristic of shock and these were confirmed later by MacCallum. With regard to treatment of shock, two excellent principles are enunciated; Frazier said, 'Begin the treatment of shock before its onset'. While Crile is of the opinion that 'the best cure for shock is prevention'.

We have only one criticism to offer against this excellent monograph. Animal experiments, we concede, are indispensable for the progress of science but there must be some limitation to brutality. 'Dogs under barbitol anaesthesia were rigidly encased in a plaster of Paris cast and one side of the animal was then burned with a Bunsen flame applied through windows in the plaster case. The bodies were bisected longitudinally and the weights of the two sides were compared'. At least six such experiments are recorded (p. 146) although it is obvious that they include an inevitable factor of error. Experiments such as these bring discredit to the medical research worker, and it is surprising that this point escaped the vigilance of the Oxford University Press. The printing, get-up and illustrations are excellent and a useful index is appended. There is also a complete bibliography on the subject.

P. N. R.

PRACTICAL OTOTOLOGY, RHINOLOGY AND LARYNGOLOGY.—By A. E. Schlanser, M.D. 1938. Henry Kimpton, London. Pp. 315. Illustrated with 81 engravings. Price, 21s.

WRITTEN by a Colonel of the United States Army Medical Corps, this book is primarily intended for the use of medical officers in that corps. However, the practical way in which each subject has been presented will have a wide appeal, especially to house surgeons and clinical assistants in ear, nose and throat departments.

The book begins with suggestions for a systematic and rapid method of case-taking and examination of a patient, and then describes the commoner conditions of the ear, nose and throat from the clinical aspect, with notes on their treatment.

Each subject is described in simple terms, unencumbered with vague alternatives or theorizing. As a result the book tends to be dogmatic in many places, but this does not detract from its value in any way; in fact the reader is inspired by a feeling of confidence in what is laid down.

The concluding chapter gives a list of instruments required for various operations. If this is the authorized equipment in the U. S. Army, our military specialists should turn green with envy.

W. McN. N.

DISEASES OF THE NOSE, THROAT AND EAR: MEDICAL AND SURGICAL.—By W. L. Ballenger, M.D., F.A.C.S., and H. C. Ballenger, M.D., F.A.C.S. Seventh Edition. 1938. Henry Kimpton, London. Pp. 1030. Illustrated with 576 engravings and 30 plates. Price, 50s.

THE new edition of this well-known book has been brought thoroughly up to date and is more worthy than ever before to be considered among the important standard textbooks on diseases of the ear, nose and throat.

In its new form the book has become appreciably enlarged through the introduction of new material; but whatever has been added has passed beyond the 'experimental' stage, and is worth careful notice.

Much of interest is to be found in the section on the paranasal sinuses, and the problem of surgical treatment of maxillary sinusitis receives special attention. In another section of the book diathermy and radium

are recommended for treating malignant tumours of the antrum.

In the section on diseases of the ear there is so much that is excellent that it is difficult to pick out portions for comment. In recent years there have been many advances in otology, and all the important ones will be found incorporated in the text. The chapters on petrositis and labyrinthitis adequately sum up the present state of knowledge on these conditions, references to the literature being given in footnotes.

Mechanical aids to hearing are not described.

The concluding chapters on endoscopy have been written by Tucker and Chevalier Jackson, and form a fitting conclusion to an excellent book.

W. McN. N.

DISEASES OF THE NOSE, THROAT AND EAR.—By W. W. Morrison, M.D. 1938. W. B. Saunders Company, Philadelphia and London. Pp. 675. Illustrated. Price, 25s.

THERE is no lack of textbooks on diseases of the nose, throat and ear, and yet the student of limited means may have some difficulty in choosing a book of moderate price and size that is sufficiently comprehensive for his needs.

Here is a book, written by an able teacher of generations of students and post-graduates, that should find instant favour.

Each section opens with a short description of the applied anatomy and physiology of the parts concerned, but the author wisely omits many of the finer details, referring the reader to the standard textbooks on these subjects.

The importance of correct technique in physical examination is recognized, and a chapter on this is to be found in the early part of each section of the book.

The various common conditions of the ear, nose and throat and their treatment are described in the usual way. The subjects are illustrated throughout by numerous really excellent line drawings executed by the author, and if any deserve special mention they are those in the chapters on diseases of the ear. Too often the aural theatre is, to the new student, a dark arena wherein may be perceived the flashing of headlights and the sound of tapping. But, once having studied the figures illustrating the operations on the ear, he should have no difficulty in appreciating what is going on.

The text is free from errors, and reading is made easy by clear type printed on good paper.

W. McN. N.

PARENTERAL THERAPY: A READY REFERENCE MANUAL OF EXTRA-ORAL MEDICATION FOR PHYSICIANS, DENTISTS, PHARMACISTS, CHEMISTS, BIOLOGISTS, NURSES, MEDICAL STUDENTS AND VETERINARIANS.—By W. F. Dutton, M.D., and G. B. Lake, M.D. 1936. Baillière, Tindall and Cox, London. Pp. x plus 386. Illustrated with 90 half-tones and line engravings. Price, 34s.

IN this book the authors have dealt with the subject of extra-oral medication, the methods of such therapy and the various preparations used parenterally.

The book is divided into three parts: part I deals with the general technique of parenteral therapy; part II is the therapeutic index and part III, the pharmacological notes. The first part contains the technical details of various methods of parenteral therapy, viz, those of giving injections, intradermal, subcutaneous, intramuscular, intravenous, intra-peritoneal, intracardiac, etc.; blood transfusion; puncture of the pericardium, artificial pneumothorax; lumbar, cisternal and intraventricular puncture and injections; intravenous, infiltration and spinal anaesthesia; injections into different nerves; injection treatment of varicose veins, haemorrhoids and also of hydrocele, hernia, bursae and naevi; administration of medicine by inhalation and ionic medication. Each subject has been dealt with in a thoroughly practical

and easily comprehensible manner. Difficulties and complications that might arise have been described.

The book is profusely illustrated and the illustrations are of practical value in helping the reader to follow the text and in explaining the technique of different procedures. The techniques described are those that the authors or other eminent specialists in the field have found to be most practical.

The therapeutic index and the pharmaceutical guide contain information which the general practitioner will find very useful. The pharmaceutical guide contains the pharmacological action of the various proprietary preparations used parenterally.

The book is very well written and we can strongly recommend it to medical practitioners and house surgeons or physicians of hospitals.

R. N. C.

ALCOHOL AND HUMAN LIFE: BEING PARTLY A REVISION OF 'ALCOHOL AND THE HUMAN BODY', BY THE LATE SIR VICTOR HORSLEY AND THE LATE DR. MARY STURGE AND OTHERS.—By C. C. Weeks, M.R.C.S., L.R.C.P. Second Edition. 1938. H. K. Lewis and Company, Limited, London. Pp. xi plus 455. Illustrated. Price, 6s.

The second edition of this book deals in very great detail with the intensely important sociological problem—alcohol as a drug of addiction. Dr. Weeks has been very conscientious and painstaking in his comprehensive survey of the problem and the fruit of his labours is characterized by arriving at definite conclusions supported by the available scientific data and statistics. The book not only deals with the physiological and pathological manifestations of indulgence in alcohol but also the legal aspects of the problem and the question circling round the taking of alcohol by motor-car drivers has been exhaustively described. The sections dealing with the use of alcohol in medical treatment, effects of alcohol on the nervous system, alcohol as a food, alcohol in the tropics, the menace of the cocktail are particularly instructive. The influence of alcohol on national life has been well surveyed and the author's contentions with regard to the deleterious effect of alcohol on the expectation of life has been supported by reference to life-tables and death rates.

The volume is well written and will serve as a book of reference to medical men interested in the problem and social workers who wish to bring before the public the harmful effects produced by alcohol.

R. N. C.

CHRONIC INTESTINAL TOXÆMIA AND ITS TREATMENT: WITH SPECIAL REFERENCE TO COLONIC THERAPY.—By James W. Wiltse, A.B., M.D. 1938. Baillière, Tindall and Cox, London. Pp. xii plus 268. Price, 13s. 6d.

ATTEMPTS have been made from time to time to incriminate stasis in the large intestine as the cause of chronic ill health but the medical profession has been rather sceptical in accepting this theory. Colonic lavage as a form of treatment has come into and gone out of favour on several occasions. Dr. Wiltse is an advocate of this form of treatment. His book, although it is probably the best written argument for the theory of chronic intestinal toxæmia, still falls far short of being convincing and satisfying. The author insists that the benefits of colonic lavage do not result from the emptying of the bowel but from 'the healing of inflamed and injured tissues, the restoration of normal mechanical and cellular function, the improvement of both capillary and lymphatic circulation and of liver function'. He also considers that the use of the enema should be strongly deprecated. The author's contention that the use of enemas tends to undo all the benefits that are derived from colonic lavage is difficult to understand although it is quite understandable that an enema cannot take the place of colonic irrigation.

The book is divided into two parts, a treatise on the anatomy of the colon and a description of the various methods of performing the lavage. So far as

the practical side of the question is concerned the author's statements are clear and easily comprehensible. It is when he approaches the theoretical background that he fails to carry conviction. The sections dealing with focal and systemic infection, bacterial and food allergy and mechanical and miscellaneous causes, all of which are illustrated with cases, will interest medical practitioners.

We are of opinion that although the case for colonic lavage still remains undecided, Dr. Wiltse's book is very interesting and it is hoped that it will be studied by those who are interested in the problem of intestinal stasis and its treatment by colonic irrigation.

R. N. C.

CLINICAL PÆDIATRICS (THE BABY).—Edited by W. R. F. Collis, M.A., M.D., F.R.C.P., F.R.C.P.I., D.P.H. 1938. William Heinemann (Medical Books), Limited, London. Pp. xi plus 460. Illustrated. Price, 21s.

This book has been written by Dr. W. R. F. Collis the paediatrician to the Rotunda Hospital, in collaboration with some of his colleagues and also other experts in charge of the various special departments of the important hospitals of Ireland. In a book of this nature, he has confined himself only to such conditions as are, in practical life, likely to face any medical man in dealing with small babies from their birth up to one year of life but leaving out of consideration diseases of the childhood period. He has also included some of the important features in connection with the neo-natal period, such as infant mortality and child welfare organizations.

As we can expect from Dr. Collis and his collaborators, the various morbid conditions to which small babies are susceptible have been dealt with from all points of view in a practical, up-to-date and scientific manner. This has been possible because of the writers' accumulated experience in one of the largest children's hospitals in the British Isles. An important feature of the book is that description and management of all possible disorders in the baby have been included and this has enormously increased its usefulness to the general practitioner who will be able to manage his little patient without having to call in a specialist.

Every chapter begins with a protocol of the subject-matter to be dealt with, a very useful and convenient summary. It is difficult to criticize any particular subject and the chapters on nutrition, vitamins, gastro-intestinal disorders, tuberculosis, infectious diseases and ophthalmic disorders are excellent. The section on diseases of the skin is specially commended not only for its wealth of useful information but also for the plethora of illustrations to help the student and the practitioner. The last good word on the book is in connection with the charts and tables which will no doubt be of great help for rapid differential diagnosis.

The reviewer feels it his duty to draw the attention of the writer to a few points which have come to his notice. In discussing the treatment of diphtheria, more detail regarding serum treatment might have been given. His statement of a 'minimum therapeutic dose of 4,000 units' is unfortunate and 'the injection of a single large dose of 60,000 units intramuscularly' in a baby is certainly not 'convenient' as written by the author. Again, 10,000 units can hardly be considered adequate for a case of nasal diphtheria. Adenitis in diphtheria may be due to toxic absorption but that the severe involvement of the glands is due to secondary invasion by streptococcus hæmolyticus is an accepted fact. In discussing the causes of convulsions, many important ætiological factors have been omitted. While he has taken great pains to mention rarities like insulin hypoglycæmia as a cause of infantile convulsion common conditions like gastro-intestinal irritations have been left out. In the same chapter the author writes of 'Königs sign' for meningitis though in all probabilities he means Kernig's sign. Although Dr. Collis has attempted to confine his book to small babies he has not been able to avoid the temptation of

taking up bigger children for his descriptions. This weakness of the author is betrayed in many places both in the text and also in his illustrations. Lastly the inclusion of only a few references in the last page of the body of the book does not seem to have added much to its scientific value.

The above comments do not in any way lower the value of this book in the estimation of the reviewer who considers it an excellent British production and a very valuable one for students and practitioners.

PRACTICAL PHARMACY—INCOMPATIBILITY AND PRESCRIPTION WRITING.—By B. Roy, L.M.F. Second Edition. 1936. Published by the author (Demonstrator of Materia Medica, Dacca Medical School). Pp. x plus 272. Illustrated. Price, Rs. 2-8. Cloth bound Rs. 2-12

IN this book an attempt has been made to present the subject of incompatibility and dispensing in a clear, comprehensive and concise manner for the students going up for the licentiate and compoundership examinations of the State Medical Faculty. The book is well written, is easily comprehensible and is well printed. The first part of the book deals with methods of dispensing and the second part contains a list of drugs with their composition, solubilities and incompatibilities. The art of writing prescriptions is very important and the author has tried to explain in the last chapter the form in which prescriptions are generally written. It is hoped that the book will prove of assistance to the class of students for whom it is intended.

'THE PREVENTION OF MALARIA INCIDENTAL TO ENGINEERING CONSTRUCTION'.—By H. W. Mulligan and M. K. Afridi. Health Bulletin No. 25, Malaria Bureau No. 13. Pp. 52, with 11 figures and 8 photos. Government of India Press, New Delhi. Price, 7 annas

At the fourth International Malaria Congress last autumn held at Amsterdam, the late Director of the Malaria Survey of India, Colonel Sinton, closed a discussion with the plaint that we are always talking about *controlling* malaria, instead of *preventing* it by controlling engineers and cultivators.

The *Bulletin* under review summarizes briefly but succinctly the major points in which the malarious activities of the engineer and the cultivator require controlling. It is written in medically non-technical language, and after consultation with three highly placed engineers, two in this country and one in Malaya, the latter being one of the few countries of the world where the engineer has long been thoroughly controlled!

With every word of the *Bulletin* we are in complete agreement, and would like to see a copy of it on the desk of every civil engineer in this country. A study of the work would save endless acrimonious discussions and much explanation by those responsible for the health of engineering projects. That engineers will listen, and can be convinced, the reviewer knows, as witness the chief engineer's circulars regarding work in malarious zones in force on the railway to which he is malariologist.

In connection with borrow-pits, rightly described as the most universal and most dangerous of all the works of man which have a direct influence on the incidence of malaria, the engineer can take refuge from some of the strictures passed upon him by allocating the blame to the accounts officer. Field measurement books have to be produced in paying for excavation, and so arise 'the chains of borrow-pits each separated from the other by a narrow wall of earth'. To interfere with the accountancy of Government is to indeed trespass on holy ground, but a revision of the code in this matter should not be beyond the wit of man to devise, though the existing code has probably been compiled so as to be as nearly fraud-proof as possible.

Both with road and railway construction, especially with the latter, the per-mile cost must be kept within

a certain figure, else financial justification for the project cannot be arrived at. By what proportion the construction of a railway to avoid making it non-malarious would be increased does not seem ever to have been worked out. Until the engineering profession will make such a calculation and find if it can be used in their own defence, they must continue to lie down to the type of stricture passed upon them by malaria control workers generally, and the authors of this *Bulletin* in particular.

R. S. W.

KER'S MANUAL OF FEVERS.—Revised by Frank L. Ker, B.A. (Cantab.), M.B., Ch.B. (Edin.). Fourth Edition. 1939. Oxford University Press, London. Pp. xi plus 354. Illustrated. Price, 12s. 6d. Obtainable from Oxford University Press, Bombay and Calcutta

THIS book has now gone through a number of editions and has always been popular with the student in Great Britain. Its usefulness in India is naturally limited. The 'fevers' that are dealt with are not the ones that first spring to the mind when the word 'fever' is used in this country, but we are beginning to realize that all these fevers do occur in India much more commonly than was supposed a few years ago. Fifty years ago, treatises were written in this journal on why only British and not Indian troops suffered from typhoid fever. Enteric is now recognized as one of the commonest causes of fever amongst the indigenous population. Again, measles is often a troublesome epidemic amongst labour forces, and in the hill stations in India scarlet fever and diphtheria are as common as in any community in Europe.

The high standard of the previous editions has been maintained, and both practitioners and students will find the book very useful.

PERSONALITY DEVELOPMENT AND SOCIAL CONTROL IN TERMS OF CONSTITUTION AND CULTURE.—By Ira S. Wile, M.S., M.D. (Three lectures at the Tavistock Clinic, July 1937.) 1939. Oxford University Press, London. Pp. 57. Price, 3s. 6d. Obtainable from Oxford University Press, Bombay and Calcutta

THIS small book is composed of three lectures with the following titles:—

1. Personality in terms of constitution.
2. Personality in relation to culture.
3. Social control and prevention of personality disorders.

They were delivered in England by this well-known American psychiatrist and student of social problems.

They deal with the effect of the environment on the behaviour of the individual and hence on the reactions of the community as a whole, and are based on persons living under European conditions so they are perhaps not fully applicable to a country such as India where the widely different social customs and religious beliefs from those of Europeans excite a correspondingly different set of reactions.

Much that these lectures contain is, however, capable of general adaptation to any race so that their perusal will be of value to social workers anywhere in the world.

THE ESSENTIALS OF MODERN SURGERY.—Edited by R. M. Handfield-Jones, M.C., M.S., F.R.C.S., and A. E. Porritt, M.A., M.Ch., F.R.C.S. 1938. E. and S. Livingstone, Edinburgh. Pp. xv plus 1126, with 501 illustrations. Price, 30s. Obtainable from Messrs. Butterworth and Company (India), Limited, Calcutta. Price, Rs. 20

TEXTBOOKS tend to run in cycles. There is a sudden spate of textbooks on some subject, then a period when these books run through numerous editions, or drop out of use, and the cycle starts again. This is natural, as in time writers find that it is difficult to fit the new material into the old frames.

Messrs. Handfield-Jones and Porritt consider that the time has come for a new textbook on surgery. Those

already in use are either frank cram books for the medical student or too pretentious tomes of many volumes for the use of the specialist. Whilst we cannot agree that all the current books on surgery fall into one of these two classes, we do consider that the authors have made a reasonably good case for the very serious step they decided to take (i.e., burdening the medical library with another book) and the result has fully justified their decision, namely, to produce a book that, whilst not being too large for the undergraduate student, will supply the student for higher degrees with the basis of his surgical knowledge, and finally be useful as a reference book to the practitioner.

Another point in favour of this book is that the authors, by writing the major portion of the book themselves have, achieved the homogeneity so desirable in a textbook, and yet have escaped the charge of omniscience and have added authoritative weight to this book by obtaining the collaboration of thirteen of their specialist colleagues. These include Dickson Wright of St. Mary's Hospital who writes on diseases of the brain, McElligott on venereal diseases, A. W. Matthew on anaesthetics, Walter Howarth on affections of the nose and sinuses, Lionel Colledge on diseases of the ear, pharynx and larynx and Tudor Edwards on diseases of the chest, lungs and pleura.

Knowledge of the local and special anatomy and pathology are an essential prelude to the full comprehension of any surgical disease and its correction; these aspects are given their due prominence in each chapter of the book. Special examinations, such as radiography, are given their place but are not over-emphasized; in fact the emphasis throughout the book is on clinical observation.

The book is well illustrated and almost without exception the illustrations are relevant and show clearly what they are meant to show; this is by no means always the case in textbooks. The publishers have produced an excellent book which is not too bulky despite its thousand odd pages of firm and completely opaque paper; the print is clear and the volume opens flat. It is a book that we can unhesitatingly recommend to the student and practitioner in India.

SURFACE ANATOMY.—By W. E. Roberts, M.R.C.S., L.R.C.P. 1937. Angus and Robertson Limited, Australia (89, Castlereagh Street, Sydney). Pp. x plus 93. Illustrated. Price, 7s. 6d.

A good book on surface anatomy is part of the necessary equipment of a medical student. If he is wise he will take great care of his copy and keep it for reference for the rest of his life.

The present volume is a good example of its class and has some outstanding features which give it special distinction, amongst these are that the full explanatory text of each figure is to be seen on the page on which the figure appears, or on the opposite page; this obviates frequent turning of pages.

The Birmingham-Revision nomenclature is used, but in places the Basle and even the old nomenclature are given in brackets.

The book is printed in Australia and is a credit to Australasian publishing.

In fairness to our reviewer, it should be stated that though this book was published in 1937, we only received our review copy on 27th March this year.]

HYGIENE.—By J. R. Currie, M.A. (Oxon.), M.D. (Glas.), D.P.H. (Birm.), M.A., F.R.C.P. (Edin.). 1938. E. and S. Livingstone, Edinburgh. Pp. xiii plus 324, with 34 figures in the text. Obtainable from Messrs. Butterworth and Company (India), Limited, Calcutta. Price, Rs. 10

This book is a short summary of hygiene written for the medical student. The information contained in this volume is sufficient for the qualifying examinations and for university degrees, but is not meant for those studying for public health qualifications.

On the whole the book serves the purpose for which it was written, very well. Much that is included will be equally useful to the student in this country, as the

administrative and legal aspects of the subject are only touched upon in a very general way.

The information in the section headed 'infestations' will not however be of much value to the worker in the tropics, or to anyone else. The statement that 'the sandfly is a minute creature, like a tiny moth', even if we forgive the obvious misprint, doesn't really help much, and the information about cockroaches might have been much more useful, even in the space allotted.

Carbon tetrachloride only is recommended for mass treatment of hookworm disease; more recent work on the subject might have been consulted. Useful information is given in the sections on the nutritive aspects of food, but the statement that maize is a nutritious food requires qualifying.

Another criticism is that the practice of italicizing scientific names of micro-organisms and insects is only fitfully adopted.

The book should however prove very useful to the undergraduate student in India.

MY TESTAMENT OF HEALING.—By J. Ellis Barker. 1939. John Murray, Albemarle Street, W.1, London. Pp. vi plus 345. Price, 8s. 6d.

It is surprising that such books as this enjoy a wide circulation in times when the general standard of education is so greatly improved compared with the time when Hahnemann first formulated the principles of homœopathy. In those days the public were not very well informed on matters of general importance, including an outline of knowledge on medical matters, and it must also be admitted that the medical profession of that era was inclined to use much too large doses of drugs. In drawing attention to this failing Hahnemann undoubtedly performed a service, as a more carefully regulated system of dosage is now in vogue, and in our opinion that is the sole contribution of homœopathy to medicine.

The reviewer is possibly one of the worst possible persons to discuss a book of this nature, from the author's point of view, because he is an 'orthodox' medical man who has spent many years on scientific research, and judging from the tone of this book the ordinary 'orthodox' practitioner is bad enough, but a scientifically trained one is infinitely worse.

However, he has read the book carefully and brought to bear on it the detached attitude that prolonged scientific training enables one to assume when considering a question not in accord with one's own views. It is impossible to commence a detailed criticism for such would require as much space as the book itself so one must be content with the summing up that it is not a book that is calculated to be of much value to practitioners or the lay public whatever form of the healing art they follow.

Abstracts from Reports

TRIENNIAL REPORT ON CIVIL HOSPITALS AND DISPENSARIES IN THE CENTRAL PROVINCES AND BERAR FOR THE PERIOD ENDING 31ST DECEMBER, 1937

THE triennium ending the 31st December, 1937, witnessed a slight improvement in medical relief in the province. The number of hospitals and dispensaries increased by 12 to 348. Two new hospitals were opened for women and ten dispensaries of the cheap plan type in rural areas. Although accommodation in hospitals continued to be limited there was a welcome increase in the number of beds by 206 [90]. The Provincial Government, however, recognize that medical relief in the province is inadequate, particularly so in rural areas. That there should be no more than one dispensary for over 44,000 persons or 283 square miles of area is a measure of this inadequacy. According to the present policy the provision of medical relief is primarily a matter of local concern. Experience

has shown that the present conditions of establishing new dispensaries, one of which enjoins on the local people to make a total contribution of Rs. 8,500, are onerous and the question of relaxing them is under consideration. It is, however, clear that this method has financial limitations and it cannot be hoped to take medical help to the masses in the thousands of villages in this manner. Government, therefore, propose to investigate the possibility of introducing a lay agency possessing certain minimum qualifications, which could serve as a 'liaison' between the people and the regular medical institutions. They are also contemplating the revival of the scheme of subsidizing medical practitioners to settle in rural areas. The report of the committee appointed to determine the place which the indigenous systems of medicine in vogue in the province should occupy in the scheme of medical relief provided by the State and to make proposals for deriving the maximum possible benefit from these systems has just been received and is under consideration.

There was an increase in the number of out-door and in-door patients from 8,770,842 and 36,031 to 9,919,060 and 44,290, respectively, and the number of operations performed, which is invariably an index of the popularity of medical institutions, from 18,553 to 34,667. These statistics are a clear indication of the appreciation by the public of the amenities provided by the hospitals and dispensaries in the province and of the necessity for their expansion.

Thanks to the special efforts of Colonel (now Major-General) N. M. Wilson, it was found possible to start anti-tuberculosis measures on systematic lines. Four fully-equipped clinics were opened at Nagpur, Jubbulpore, Amraoti and Raipur. Forty beds have been reserved by Government in the Pendra Road Sanatorium which is managed by the United Board of Eleven Missions. It is, however, obvious that we have merely touched the fringe of the problem and that more organized and sustained action is necessary for combating this scourge.

Another important problem, is the treatment of eye diseases. It has been noticed that there are a few well-equipped dispensaries for the treatment of minor diseases of the eye, but that the arrangements for

Dispensary Committee Hospitals was revised and the number of such nurses was increased from 5 to 12. Forty probationary nurses are under training at the four provincialized hospitals. Training facilities exist also at some of the Dufferin Fund Hospitals in the province. It is, however, unfortunate that there is still a great paucity of suitable candidates.

Although the total expenditure on medical institutions showed an appreciable increase to Rs. 41.61 [Rs. 36.71] lakhs, it still bears an unduly small proportion to the total expenditure of the province and the local bodies. There is vast scope for improvement in the department, but progress is hampered by lack of funds. Apart from occasional generosity from individuals, the public as a whole have not yet awakened to their responsibility in the matter. It is disheartening to find that the landlord and merchant classes who can well afford to show a little charity are found to evade the payment of even legitimate dues. It is time the public realized that the state and local bodies' hospitals are intended for the poor and that the well-to-do classes must pay for the medical treatment they receive. Local bodies must also make adequate provision in their budget for medical relief and must pay their contributions to the hospitals and dispensaries regularly. They would do well to bear in mind the suggestion of the Inspector-General of Civil Hospitals that a definite percentage of their income should be earmarked for medical relief.

SEVENTIETH ANNUAL REPORT OF THE DIRECTOR OF PUBLIC HEALTH OF THE UNITED PROVINCES FOR THE YEAR ENDING 31ST DECEMBER, 1937

In the statement below are compared the death rates per mille of the population from the most important diseases during 1936 and 1937 and the average death rates for the preceding ten years. The figures for 1937 as compared with 1936 show a decrease under all heads except 'plague', 'dysentery and diarrhoea' and 'respiratory diseases', while compared with the decennial average there is an increase under the head 'respiratory diseases' only.

Chief causes of mortality	Death rate per mille for 1936	Death rate per mille for 1937	Average death rate for preceding ten years 1927-36	Increase or decrease as compared with 1936	Increase or decrease as compared with decennial average
Cholera	0.14	0.13	0.60	- 0.01	- 0.47
Smallpox	0.30	0.07	0.22	- 0.23	- 0.15
Plague	0.15	0.50	0.61	+ 0.35	- 0.11
Fever	17.60	16.37	18.30	- 1.23	- 1.93
Dysentery and diarrhoea	0.34	0.35	0.37	+ 0.01	- 0.02
Respiratory diseases	0.89	0.92	0.79	+ 0.03	+ 0.13
Injuries	0.44	0.43	0.44	- 0.01	- 0.01
All other causes	2.75	2.61	2.76	- 0.14	- 0.15
All causes	22.61	21.38	24.04	- 1.23	- 2.66

treating serious cases are not satisfactory. Six assistant medical officers were given special training for a period of six months at the Mayo Hospital and three more are under training at present. The former have been sent out to selected places in the *mofussil* where eye centres have been established. A scheme for the establishment of an up-to-date eye hospital to be financed out of the King George V Memorial Fund is also under consideration. The C. P. and Berar Blind Relief Association is doing useful propaganda and helping the blind.

The strength of the nursing staff in all hospitals continues to be inadequate. For financial reasons most of the hospitals are not in a position to employ staff nurses. The scheme of appointing staff nurses for

Epidemic dropsy.—The total number of deaths reported from the disease during the year under review was 64 against 145 last year. Out of 64 deaths, 26 occurred in rural areas and 38 in urban areas.

The highest mortality (14) was reported from the Jhansi district, followed by Benares town with 13 deaths, Allahabad town with 6 deaths and Cawnpore town with 4 deaths. In other infected towns and rural tracts of districts the number of deaths reported did not exceed 3 in any case.

The disease was fairly widespread in the cities of Benares, Allahabad and Cawnpore and consequently an officer of this department was placed on special duty to investigate the causes of the disease in those places and to suggest suitable preventive measures.

The principal findings of this investigation are as follows:—

Benares.—The largest incidence of the disease was amongst the Bengali community although it was found to a smaller extent among the general population. It affected the poor and the middle-class people mostly. Both sexes and all ages appear to be equally affected.

The factors responsible appear to be both food deficiency and food intoxication.

Allahabad.—The disease was mostly confined to the Bengalis of middle and well-to-do classes and males and females were equally affected. Children under 10 years were affected much less than those above this age.

Sixty-five per cent of the cases studied used mustard oil from one source. The outbreak in Allahabad appeared to be more of food intoxication than of food deficiency.

Cannanore.—The disease affected all the communities but the largest number of cases were found among the Mohammedans. The disease was not confined to the Bengalis, 97.5 per cent of cases having occurred amongst United Provinces men. It affected chiefly partial rice eaters and mustard oil users but a few cases have also occurred among non-rice eaters and those who do not use mustard oil. Both vegetarians and non-vegetarians have suffered but the incidence was greater among the latter and both sexes have suffered but males are affected more than females.

Village latrines.—In the 'trench pattern' latrines that have for many years been used in the United Provinces in temporary aggregations of population, the excrement has not to be carried away. All that is necessary is to cover the trench after use by earth heaped up near it, and to dig another trench and shift the screens. The use of this type of village latrines was first recommended by this department in 1935. After two years' trial they were not found to suit village conditions, because the people were unwilling to cover up the used trenches or to touch or shift the screens from them. The trenches also got filled up in rains; the screens and partitions, which were made of straw, were sometimes blown away by winds or damaged by cattle.

In the circumstances the rural health staff have now been instructed to advise the construction of bored hole latrines, of which a large number have been constructed in the health unit in Partabgarh (U. P.), in South India and in other parts of the world. The cost of each such latrine is Rs. 5. For an ordinary family one latrine should suffice for one to three years, depending upon the nature of the soil and the number of persons using it. These latrines, if properly made, should not breed flies or give offensive smell, because of their depth. They require very little space and do not require the services of sweepers, since there is nothing to clean or take away. After the bore in use is nearly full, the latrine is required to be closed and another bore is used. After six months the material in the first bore under normal conditions should be reduced to innocuous poudrette which can be dug up and the material can be used as fertilizer. This large scale experiment is being watched carefully.

Health unit in Partabgarh district.—This scheme continues, with the financial co-operation of the Rockefeller Foundation of the United States of America. The Foundation kindly extended financial support for the sixth year of this scheme, commencing 18th July, 1937.

A preliminary survey of the health conditions in the area comprised in the unit was undertaken in 1932-33, at the commencement of this work. To judge the progress made during the period of four years, a re-survey was undertaken in 1937, which reveals remarkable progress in all directions. For instance, the number of windows and ventilators in village houses has increased by over 52 per cent and that of parapet walls over drinking water wells by over five times. The number of soakage-pits, health societies and village dispensaries now is several times that existing at the time of the original survey. A fair proportion of cattle-sheds previously situated inside the dwelling houses have been separated, excavations have been filled

up in large numbers and the vast majority of manure heaps have been removed from within the habitation. New features introduced since the inception of the health unit are 102 bored-hole latrines for individual houses. Each village in the unit now has at least one improved type of well, a standard manure-pit, an approved type of soakage-pit, an improved cattle byre and some inexpensive windows and ventilators to serve as models.

Village health leagues.—The essential condition for the success of measures designed to improve rural sanitation is the willing assistance of the people, because no health organization by itself can do all that is necessary in this respect, and to continue it for all time. Experience has also shown that if the villager contributes even a little, he will feel a personal interest in, and responsibility for making the work a success. How to secure such co-operation has been a problem. A method which is being practised in the health unit area in Partabgarh with success is to arrange through a member of the health unit staff, usually the sanitary inspector for each village to form itself into a small health organization, called a 'health league' and by means of this league to take charge of and complete a series of village health problems. The membership of the league is often the entire population of the village but it usually has a small executive committee. It is the duty of the health unit staff to provide the league with a list of the health problems of the area in due order of their importance. The leagues are advised not to carry on more than one activity at one time, and to complete each activity before attempting another. In this way the too common custom of starting too many activities at the same time and of completing none is avoided. The method is recommended to rural health workers in other parts of the province.

School hygiene and medical inspection of school children for the year 1937-38.—The detailed examination of boys was conducted in 154 out of 155 Anglo-vernacular schools in the larger municipalities where whole-time school health officers are employed. The number of boys whose medical history sheets were filled was about 17,600 out of 54,300 on roll, the enrolment having increased by about 300 since last year. Out of 460 primary and vernacular schools, 187 were visited. Ordinary examination, consisting of noting main defects, of more than 12,200 boys out of 47,200 enrolled was done. About 1,900 boys were examined as 'special cases' and over 7,400 boys were re-examined.

It has been calculated roughly that 34 per cent of all the boys examined have one defect, 13 per cent have two defects and 7.5 per cent have more than two in urban areas so that there were not less than 54.5 per cent defectives to share all the defects. These figures for rural areas are (1) 12.9 per cent, (2) 3.8 per cent, and (3) 1.7 per cent giving 18.4 per cent defectives to share all the defects.

Poor nutrition.—In the larger urban areas this defect was found in 12 per cent against 13.9 per cent in 1932. This percentage does not seem to vary much in rural areas being 18.3 per cent against 19.19 per cent and 20 per cent in 1931-32 and 1932-33 respectively. The incidence of the largest number of ill-nourished children has been in the age group of 6 to 11 years. It is in all cases due to faulty nutrition.

The scheme of free supply of milk to ill-nourished and poor children was in force in towns where the central school dispensaries existed and several school health officers have made particular inquiries and observations on the effect of milk. The total number of poor and ill-nourished boys fed on milk was 861.

The school health officer, Lucknow, reports that free supply of pasteurized milk was made to 205 students in 14 different institutions at the rate of $\frac{1}{2}$ lb. daily to each student during the school hours. The record of his observations shows a total gain of 12 $\frac{1}{2}$ lb. per 100 lb. of the body weight in students fed on milk as compared to 7 lb. in the controls. One of the schools in Lucknow realizing the importance of milk feeds to students has started its own dairy.

The school health officer, Benares, observes that where pasteurized milk was supplied free to 275 students in nine institutions with a total of 120,201 meals of $\frac{1}{4}$ seer to each student daily for an average of 20 to 60 days, 73.8 per cent of the boys gained in weight. The average gain in weight varied from 1.4 lb. to 5.9 lb.

In Agra and Cawnpore pasteurized milk was supplied free to 175 and 206 students, respectively, for short periods.

The school health officer, Shahjahanpur, has worked out a nutritional quotient to serve as a guide to the progress in the health of the school child. It is a figure arrived at by dividing the weight of the child by the height of the same individual. The nutritional quotient thus worked out for the boys in the Shahjahanpur municipality when compared with those of other countries, for example, America and England, is very much less.

TWELFTH ANNUAL REPORT OF THE RAMA-KRISHNA MATH CHARITABLE DISPENSARY, BRODIE'S ROAD, MYLAPORE, MADRAS, FOR THE YEAR 1938

THE charitable dispensary conducted by the Math was started in 1925 when Rao Sahib Dr. B. Raghavendra Rao, retired civil surgeon of Madras, placed his voluntary service at the disposal of the institution, and undertook to meet the then recurring expenditure required for the work.

The following tabulated statement of the number of patients treated since the start of the dispensary up to the current year bears ample testimony not only to the utility of the institution and the growth of its work, but also to the increasing responsibilities of the management.

Year	New number	Repeated number	Total
1926 ..	3,158	1,951	5,109
1927 ..	4,873	4,541	9,414
1928 ..	8,994	9,228	18,222
1929 ..	14,630	16,302	30,932
1930 ..	26,632	27,935	54,567
1931 ..	23,442	35,463	58,905
1932 ..	21,405	31,882	53,287
1933 ..	26,537	40,384	66,921
1934 ..	27,831	41,082	68,913
1935 ..	27,659	41,008	68,667
1936 ..	28,540	44,575	73,115
1937 ..	29,241	52,770	82,011
1938 ..	33,746	59,904	93,650

The work of the dispensary has increased and the number of patients has gone up so much that the need is felt of establishing it on a firm basis financially so that the fluctuations of door-to-door collections of small amounts may not compel us to limit our services to the poor.

We appeal to the generous public to continue their active sympathy and co-operation, and to come forward with liberal contributions for fulfilling the immediate needs of the institution. Donors wishing to perpetuate the memory of their friends or relatives may do so by creating memorial endowments for the maintenance of the charitable dispensary. A tablet bearing the names of the persons whose memory is to be perpetuated will be fixed in a suitable part of the building. Contributions, however small, will be thankfully received and acknowledged.

THE THIRD ANNUAL REPORT OF THE BENGAL OBSTETRIC AND GYNÆCOLOGICAL SOCIETY FOR 1938

THERE were altogether five clinical meetings during the year. Two of the lectures were delivered on

invitation—one by Dr. F. A. E. Crew, Professor of Animal Genetics, Edinburgh, and the other by Dr. Heyman of Radium Hemmet, Stockholm, Sweden. The remaining three lectures were delivered by members of the society. All the lectures were well attended and highly appreciated.

The following is a list of the clinical meetings held:—

1. Biological tests for the diagnosis of pregnancy by F. A. E. Crew of Edinburgh.
2. Cancer campaign in Sweden by Dr. Heyman of Stockholm.
3. An interesting case of cervical polyp by Dr. J. Chakraverti.
4. Photographic demonstrations and discussion on some interesting gynecological specimens by Drs. G. C. Nandi and S. K. Ghosh.
5. Eclampsia in Bengal by Dr. J. Chakraverti. The first of the above two meetings was held under the joint auspices of the Society and the Indian Medical Association and the second and fourth with the Calcutta Medical Club.

The third All-India Obstetric and Gynecological Congress will be held under the auspices of the Bengal Obstetric and Gynecological Society during the winter of 1939.

The executive committee takes this opportunity of reminding the members of the society that success of the Congress depends on the hearty co-operation of its members and earnestly requests their active co-operation in the matter.

Correspondence

PYOCOELE OF THE CANAL OF NUCK

To the Editor, THE INDIAN MEDICAL GAZETTE

SIR,—The following may be of interest as no reference to such a condition can be found in any of the textbooks at our disposal.

An Indian girl, aged four, was admitted to hospital on 12th March, 1939, with a swelling in the anterior part of the right labium majus extending upwards in the inguinal canal; duration several months. A diagnosis was made of anterior labial hernia or hydrocele of the canal of Nuck. Cough impulse or its absence could not be elicited due to non-co-operation on the part of the child.

At operation a condition of pyocoele was found, the pus being streptococcal, and we described the condition as pyocoele of the canal of Nuck. The sac complete with purulent contents was removed. None of us have heard or read of such a condition and consider that it must be of excessive rarity especially in such a young child; but perhaps some of your readers may recall a similar case.

Yours, etc.,

H. S. SMITHWICK,
MAJOR, I.M.S.,
and

B. W. MARATHE. S.M.S.

CIVIL HOSPITAL,
SHOLAPUR,
INDIA,

14th March, 1939.

IS IT PELLAGRA?

To the Editor, THE INDIAN MEDICAL GAZETTE

SIR,—Going through the article on 'Notes on Cases of Pellagra encountered in Calcutta' by Sen Gupta, Rai Chaudhuri, Choudhuri, and Napier (*Indian Med. Gaz.*, March 1939) reminds me of two cases somewhat akin to the cases mentioned.

One was a case of chronic diarrhoea in an old man of 63 years—constitution weak and anæmic. Later on, he developed œdema of the feet. He was under my treatment for a month. He was then put on astringents,

emetine, diuretics, sedatives, etc., all to no effect. He then had a change of doctor. That was proved of no avail. Ultimately, he resigned himself to my treatment in despair. By accident I prescribed him marmite in a fair dose. In a week his oedema subsided and diarrhoea diminished and in course of two more weeks he was his original self with added flesh to his old cheeks.

The other was a young widow of some 26 years. She had a chronic sore and denuded tongue. She could hardly take anything. For months together she was on bland liquid diet. Glycothymolin, glycerin, and tincture of myrrh were painted to no purpose. Astringents, like argentum nitras, in a lotion were applied. This also was of no avail. Here again I chanced to prescribe her marmite. She was all right in two weeks without any relapse for the last three years.

I am at my wits' end now to know if they are to be classed as pellagra. But this much I can say, that vitamin-B deficiency causes a sort of ulceration of the gut. This was shown by Dr. D. D. Bhattacharya, M.A., of Lucknow Medical College—a research worker there—to me. He fed a lot of guinea-pigs on different avitaminous diets, and on autopsy such ulcerations were evident.

Yours, etc.,

MANINDRANATH GHOSH, M.A.

135D, HARISH MUKHERJEE

Road,
CALCUTTA.

22nd March, 1939.

THE TREATMENT OF LOBAR PNEUMONIA

To the Editor, THE INDIAN MEDICAL GAZETTE

SIR,—With reference to your Editorial in the *Indian Medical Gazette* of October last, a special perforated nasal catheter is now available; it is made in Germany and bears the words 'Rosch Anskochbar' B6. Ordinary rubber catheters when perforated may inconvenience patients, as the punctured holes at times are not smooth, while the perforations, which are all round the tip of the catheter mentioned by me, are very smooth and have never inconvenienced my patients.

Yours, etc.,

CAPTAIN N. D. BANERJI, A.I.R.O.,
M.B., B.S.

RESIDENT MEDICAL OFFICER,
J. K. GROUP OF MILLS,
CAWNPORE,
24th March, 1939.

Service Notes

APPOINTMENTS AND TRANSFERS

LIEUTENANT-COLONEL E. COTTER, Deputy Public Health Commissioner with the Government of India, is appointed to officiate as Public Health Commissioner with the Government of India, with effect from the 24th March, 1939, *vice* Colonel Sir Alexander Russell, C.B.E., K.H.S., granted leave.

On the termination of special duty as Secretary to the All-India Inspectors-General of Prisons Conference, Lieutenant-Colonel P. D. Chopra assumed charge of the office of Superintendent, New Central Jail, Multan, on the afternoon of the 11th February, 1939.

The Governor is pleased to appoint Lieutenant-Colonel T. C. Boyd, Principal, Medical College, and Superintendent of the Medical College Hospitals, Calcutta, to act as Surgeon-General with the Government of Bengal, *vice* Major-General P. S. Mills, C.I.E., granted leave, or until further orders.

Lieutenant-Colonel J. C. De, Civil Surgeon, 24-Parganas, on relief, is appointed to act as Principal,

Medical College, and Superintendent of the Medical College Hospitals, Calcutta, *vice* Lieutenant-Colonel T. C. Boyd, or until further orders.

Lieutenant-Colonel S. Nag, on the expiry of his leave, is appointed to be Civil Surgeon, 24-Parganas, temporarily, *vice* Lieutenant-Colonel J. C. De, or until further orders.

Lieutenant-Colonel V. Mahadevan, Professor of Operative Surgery, Medical College, and Surgeon, Government General Hospital, Madras, to act as Professor of Surgery, Medical College, Surgeon and Superintendent, Government General Hospital, Madras, with effect from the date of taking charge, *vice* Lieutenant-Colonel M. M. Cruickshank proceeding on leave.

Lieutenant-Colonel T. S. Shastri, District Medical Officer, Tinnevely, Superintendent, Government Headquarters Hospital, and Medical Officer, Borstal School, Palamcottah, to act as District Medical Officer, Kistna, and Superintendent, Government Headquarters Hospital, Masulipatam, with effect from the 1st April, 1939, *vice* Lieutenant-Colonel K. V. Ramana Rao transferred.

Lieutenant-Colonel K. V. Ramana Rao, District Medical Officer, Kistna, and Superintendent, Government Headquarters Hospital, Masulipatam, to act as District Medical Officer, Tinnevely, Superintendent, Government Headquarters Hospital, and Medical Officer, Borstal School, Palamcottah, with effect from the date of taking charge, *vice* Lieutenant-Colonel T. S. Shastri transferred.

Major J. F. Shepherd, District Medical Officer, North Arcot, and Superintendent, Government District Headquarters Hospital, Vellore, to act as Senior Specialist in Surgery, Surgeon, Government General Hospital, and Professor of Operative Surgery, Medical College, Madras, with effect from the date of taking charge, *vice* Lieutenant-Colonel M. M. Cruickshank and Lieutenant-Colonel V. Mahadevan.

The services of Major W. F. Cooper are replaced at the disposal of the Defence Department, with effect from the afternoon of the 30th December, 1938.

Major E. A. O'Connor, an Officiating Agency Surgeon, on return from leave, is posted as Civil Surgeon, Quetta-Sibi, with effect from the afternoon of the 8th March, 1939.

Major M. L. Ahuja, an Officer of the Medical Research Department, is appointed Officiating Assistant Director, Central Research Institute, Kasauli, with effect from the 10th March, 1939.

Major C. K. Lakshmanan, Port Health Officer, Calcutta, is appointed to officiate as Deputy Public Health Commissioner with the Government of India, with effect from the 24th March, 1939.

Major S. Annaswami made over charge of the Midnapore Central Jail to Captain J. W. D. Goodall in the afternoon of the 19th March, 1939.

Major G. B. W. Fisher, Civil Surgeon, Bakarganj, on relief, is appointed to be Civil Surgeon, Jalpaiguri.

Captain J. Edis Myers, on return from leave, to act as District Medical Officer and Superintendent, Government Headquarters Hospital, Bellary, with effect from the date of taking charge.

Subject to the approval of the Secretary of State for India to the transfer to the Civil Branch of the Indian Medical Service of Captain J. H. Gorman, that officer is appointed as a leave reserve officer under the Central Government and is attached, until further orders, to the office of the Port Health Officer, Bombay, with effect from the 6th February, 1939.

Captain J. W. D. Goodall, Civil Surgeon, Midnapore, is appointed to act as Superintendent, Midnapore Central Jail, during the absence, on leave, of Major S. Annaswami, in addition to his own duties.

Captain F. W. Allinson, Civil Surgeon, Darjeeling, on relief by Major J. C. Drummond, was posted to the Presidency General Hospital as First Resident Medical Officer.

Captain W. M. Niblock, Second Resident Medical Officer, Presidency General Hospital, is appointed to act as First Resident Medical Officer of that institution, during the absence, on leave, of Captain Allinson

His Excellency the Governor of Bengal is pleased to appoint Captain P. I. Franks to be Surgeon on His Excellency's personal staff, with effect from the 24th February, 1939.

The following appointments are made:—
(Short Service Commission)

To be Lieutenants

Dated 12th January, 1939

Inderjit Singh.
Dipak Bhatia.
Nowshir Dinshaw Piroshaw Kurani.

Dated 1st February, 1939

Nowshir Jungalwalla.
Dharam Dev Verma.

The undermentioned appointment is made:—

To be Lieutenant (on probation)

1st January, 1939

Oliver Turquand Mansfield (secd.). (In substitution of the previous notification.)

LEAVE

The Governor is pleased to grant leave for 6 months to Major-General P. S. Mills, C.I.E., Surgeon-General with the Government of Bengal, with effect from the date on which he is relieved.

Colonel Sir Alexander Russell, C.M.E., K.H.S., Public Health Commissioner with the Government of India, is granted the following leave:—

- (i) Leave on average pay for 3 months and 22 days from the 24th March, 1939, to 21st April, 1939, and from the 18th May to 9th August, 1939, and
- (ii) Leave on half-average pay for 20 days from the 10th August to 29th August, 1939.

Lieutenant-Colonel E. W. O'G. Kirwan, C.I.E., Professor of Ophthalmic Surgery, Medical College, Calcutta, is granted leave for 6 months, with effect from 24th March, 1939, or from any subsequent date on which he was relieved.

Major E. G. Montgomery, Civil Surgeon, Dacca, is granted leave for 15 months, with effect from the 21st October, 1938.

Previous notification is hereby cancelled.

Major C. V. Falvey, Civil Surgeon, Bareilly, proceeded on 1 year's medical leave from 27th January, 1939, afternoon.

Major S. Annaswami, Superintendent, Midnapore Central Jail, is allowed leave on average pay for 3 months from the 15th March, 1939, or on any subsequent date on which he avails himself of it.

Major V. Aitchison, Civil Surgeon, Cawnpore, proceeded on 27 months and 22 days' combined leave pre-retirement, with effect from 1st March, 1939.

Captain F. W. Allinson, First Resident Medical Officer, Presidency General Hospital, is granted combined leave *ex-India* for 1 year, with effect from the 1st March, 1939, or any subsequent date on which he avails himself of the leave.

Captain B. A. Porritt, Acting District Medical Officer, Tanjore, is granted leave on average pay for 1 month and 11 days and military furlough for 19 days in continuation with effect from 6th May, 1939, or date of relief.

Captain F. H. A. L. Davidson, Civil Surgeon, Jalpaiguri, is granted leave for 1 year, with effect from the date on which he was relieved.

RETIREMENTS

Lieutenant-Colonel C. M. Plumtre is permitted to retire from Government service, with effect from 27th March, 1939, instead of from 27th December, 1939.

Lieutenant-Colonel B. Gale retires, 31st January, 1939.

Notes

ARMY AND NAVY STORES, LIMITED

THE Society has now at its London address a die of the badge of the 'Indian Medical Service', and a supply of the correct coloured ribbon available for the production of private Christmas cards; it is thought that this may be useful to officers of the Service who are on leave in England and require such cards.

MARMITE IN TROPICAL MEDICINE

NUTRITIONAL diseases are particularly common in tropical and sub-tropical countries, where the diets of the people are so often inadequate, and the prominent part played by deficiency of vitamin B₁ and the B₂ complex is attracting the notice of research workers and of government authorities. The special applicability of marmite, whether used as a medicine or as a food, in India and other tropical countries depends not only on its proved medicinal properties, but also on the fact that it is purely vegetable in origin and may therefore be taken freely by all those who, for religious or other reasons, insist upon a strictly vegetarian diet. Another point of practical importance is that it is economical in use and is not affected by climatic conditions.

Marmite is prescribed prophylactically and therapeutically in many countries including India, Burma, Malaya, China, Java, Egypt and Africa, its specific use in tropical medicine being to combat beri-beri, pellagra and tropical macrocytic anaemia.

Publishers' Notice

SCIENTIFIC Articles and Notes of interest to the profession in India are solicited. Contributors of Original Articles are entitled to receive 25 reprints *gratis*; additional reprints can be obtained on payment. No reprints will be supplied unless contributors ask for them at the time of submitting their manuscripts.

Communications on Editorial Matters, Articles, Letters and Books for Review should be addressed to THE EDITOR, *The Indian Medical Gazette*, c/o The Calcutta School of Tropical Medicine, Central Avenue, Calcutta.

Communications for the Publishers relating to Subscriptions and Advertisements should be addressed to THE PUBLISHERS, *The Indian Medical Gazette*, P. O. Box No. 54, Calcutta.

Annual Subscription to '*The Indian Medical Gazette*', Rs. 16 including postage, in India. Rs. 19-8 including postage, abroad. Single copies Re. 1-8 each. Back numbers (if available) for the previous year Rs. 2-8 each, and all other back numbers Rs. 5 each.

Subscribers who so desire may have their copies packed flat in a strong envelope. The extra charge per annum is Re. 1-8 which should be added to the subscription. The envelopes are strongly made, and the *Gazette* is not folded, nor creased, in transit.

Papers and articles forwarded for publication are understood to be offered to *The Indian Medical Gazette* alone, and any breach of this rule will be followed by non-publication. When any such article appears in the *Indian Medical Gazette*, the copyright automatically becomes the joint property of the author or authors, and of the publishers.

The Editors of *The Indian Medical Gazette* cannot advise correspondents with regard to prescriptions, diagnosis, etc., nor can they recommend individual practitioners by name, as any such action would constitute a breach of professional etiquette.

PRONTOSIL IN INDIAN STRAINS OF MALARIA

By R. N. CHOPRA, C.I.E., M.A., M.D., Sc.D. (Cantab.),
F.R.C.P. (Lond.)

BREVET-COLONEL, I.M.S.

Honorary Physician to the King

B. M. DAS GUPTA

B. SEN, B.Sc., M.B.

and

R. T. M. HAYTER, M.B.E.

(School of Tropical Medicine, Calcutta)

THE discovery of antimalarial properties in plasmochin and acridine derivatives such as atabrin is undoubtedly a great advance in the therapy of malaria. The untoward symptoms which are occasionally observed, their inability to prevent relapses in a certain percentage of cases and their not having a true prophylactic action, inasmuch as they have no action on the sporozoites injected by the mosquitoes, have however necessitated a vigorous search for drugs which may be free from these disadvantages. A large number of synthetic compounds have therefore been tried in malaria, but so far plasmochin and atabrin have held the field. For the last few years some of the compounds prepared from azo-dyes have been the subject of intensive study on the part of chemists, experimental pathologists and clinicians. Sulphanilamide is the name adopted by the Council of Pharmacy and Chemistry of the American Medical Association as a convenient abbreviation for p-amino-benzene sulphonamide, which has been shown to be the active portion of the molecule of prontosil, a drug which was first introduced by Damagk in 1935. A number of new compounds have since been produced whose activity depends on the presence of this molecule, and which are being extensively used by the medical profession in various infective conditions with remarkable success. These compounds have also been tried in the treatment of malaria and the views which have been expressed with regard to their efficacy in this disease are divergent. For instance, Díaz de León (1937), who was the first to carry out trials in malaria, treated 15 cases with apparently good results. The drug was administered by the mouth excepting in a severe case where he had recourse to an injection of 10 c.cm. of a 5 per cent solution, in addition to the usual administration by the mouth. Hill and Goodwin (1937) in the same year treated 100 cases of malaria with intramuscular injections of prontosil every twelve hours and found that 4 injections sufficed to produce satisfactory results. Read and Pino (1938), however, did not obtain encouraging results. They treated 3 cases of malaria with

the initial doses of 6 tablets (1.8 gm.) in 24 hours; afterwards the dosage was reduced to 3 tablets a day. Patients showing gastric symptoms were given intramuscular injections. These workers observed that sulphonamide has anti-malarial action of a mild order inasmuch as it has neither a sufficiently definite action on the cycle of schizogony nor has it remarkable properties as a gametocide. Pakenham-Walsh and Rennie (1938) treated a case of induced malaria with prontosil by giving 3 gm. of the drug daily for 3 days. The temperature came down and the parasites disappeared, but a week later, the fever relapsed and the parasite counts were nearly as high as in the original attack.

Das Gupta and Chopra (1938) tested the efficacy of prontosil in monkey malaria. They found that in doses of 0.5 to 1 c.cm., given intramuscularly, the drug failed altogether to check the multiplication of *P. knowlesi* in the rhesus monkey. The disproportionately heavy doses of 3 c.cm., however, proved effective. Trials were then carried out in the Carmichael Hospital for Tropical Diseases on a series of cases of human malaria with a view to seeing how effective the drug was in Indian strains of malaria if administered in such therapeutic doses as are effective in streptococcal infections. In the present paper the results of these trials have been recorded.

The patients were all admitted to the hospital and, with the exception of those showing urgent symptoms, the antimalarial treatment was withheld for a few days in order to select only those cases which did not show any tendency to spontaneous recovery. Approximate estimations of the number of parasites were daily made during this period and the treatment was started when the parasite counts were fairly uniform for two or three days. Daily examinations of the blood for malaria parasites were carried out during the course of treatment and also for a few days after the treatment was completed. The effects of the drug were carefully studied on (i) temperature, (ii) the sexual and the asexual forms of the parasites and (iii) the time taken for the disappearance of the parasites from the peripheral blood. Any untoward effects produced were recorded. Whenever possible, the patients were kept under observation for a fortnight or so after the treatment was completed and the cultural examinations of blood were also carried out in a number of cases to determine if the infection had been eradicated.

In the present series oral administration was the usual procedure but a perusal of the table will show that injections were also given in three cases. We first started with one tablet (0.5 gm.) three times a day for five days and later increased the dose to 2 tablets four times a day. In the one quartan case in this series the drug was continued for seven days. The injections were given intramuscularly in the gluteal region,

TABLE

9	M., M., 9	M. T.	Sc.	Sc.	Sc.	Sc.	Sc.	Sc.	0	Sc.	0	Sc.	One tab. three times a day for 5 days. Apyrexial when treatment was started. Crescents persisted. Observed for 20 days; no relapse.	

the dose being 5 c.cm. of a 5 per cent solution for five consecutive days.

The table shows that prontosil does cause disappearance of the parasites from the peripheral blood; in cases of infection with *P. falciparum* the asexual forms were destroyed within 2 to 6 days but the sexual forms remained unaffected (cases 2, 3, 4, 5, 6, 8, 9, 10, 11, 13, 14, 17 and 18). In infection with *P. vivax* both the asexual and sexual forms disappear from the peripheral blood within 2 to 5 days (cases 1, 2, 12, 16, 17 and 19). Unfortunately "only one case of pure quartan infection was admitted during the period of investigation and the effect of prontosil on both the asexual and the sexual forms of this species was found to be much less marked than on the other two infections, the parasites persisting for a comparatively longer period. It is also evident from the table that the patients who were given smaller doses of the drug (0.5 gm. three times a day for five days) were relieved of the symptoms and the blood was negative for malaria parasites, but the patients relapsed during their stay in the hospital. No relapse, however, occurred in those patients who received a higher dose (one gm. four times a day for five days), with the exception of one case who gave the history of long duration. In the present series, prontosil, administered by injection, did not prove to be as effective as when given by the mouth.

The untoward effects which were observed in a certain number of cases during the course of administration of prontosil were of mild character, and beyond slight epigastric distress and flatulence no toxic effects were recorded. One of the patients showed great sensitiveness to the drug and it had to be stopped.

Summary and conclusions

(1) Prontosil in ordinary therapeutic doses (3 to 4 gm. daily for five days) has an undoubted action in causing disappearance of malarial parasites from the peripheral blood and in controlling symptoms of the disease.

(2) It destroys both the asexual and sexual forms of *P. vivax* and *P. malariae* and only the asexual forms of *P. falciparum*. It has no action on the crescents. Its action on *P. malariae* appears to be comparatively slower and less potent.

(3) In smaller doses (1.5 to 2.0 gm. daily for five days) the symptoms of the disease abated and the parasites disappeared from the peripheral blood but recrudescence of the disease occurred within a fortnight.

(4) Prontosil undoubtedly possesses mild antimalarial properties in infections with Indian strains of malaria and is worthy of trial when other antimalarial drugs are not available or are contraindicated.

The series is very small and the conclusions are only tentative.

THE CALCIUM AND PHOSPHORUS CONTENT OF STUDENTS' DIETARIES

By K. C. SAHA

K. L. ROY

and

B. C. GUHA

(From the University College of Science, Calcutta)

EARLIER work (Pal and Guha, 1937) had indicated the probability that the diet consumed by middle-class people in Calcutta was appreciably deficient in calcium. We sought to obtain further information on this question by investigating the cooked diets consumed by general middle-class students in some of the hostels of Calcutta. Eight hostels were chosen and the cooked diets, consisting of the chief day and evening meals, were analysed to find the average consumption of calcium and phosphorus per head per day. As the bulk of the daily diet was composed of rice, it was considered desirable to estimate the phytin phosphorus of the diet, for phytin phosphorus is not available for nutrition and should be subtracted from the total phosphorus. An aliquot of the total mixed diet, meant for one average individual, was analysed as was done in previous work (Guha, 1934). The figures for calcium (in terms of CaO) and phosphorus are given in table I. The values for phytin phosphorus and total phosphorus obtained on those days, on which both of them were estimated in the same diet, are given in table II. A statistical note on the significance of the results by Mr. K. C. Basak is also given.

Thus the mean values for calcium and phosphorus content per head per day, considering all the hostels and all the days, are 0.636 and 1.01 gm. respectively.

Statistical note

The following two analyses of variance do not show any significant difference in the average calcium oxide and phosphorus contents of the diets of the different hostels.

It will be noticed that in both the cases the mean square within hostels is greater than that between hostels. This shows that the greater part of the variation is due to the daily variation in the amount of CaO and phosphorus in the diet of each hostel.

Discussion and summary

It is clear from the statistical analysis of the results that the variations in the consumption from hostel to hostel are not great. The results can, therefore, be reasonably accepted as indicating the average consumption of calcium and phosphorus by the student population of Calcutta living in hostels. The consumption of Ca (0.636 g. per head per day on an average) appears to be appreciably lower than the optimum intake, which is usually accepted to be of the order of 1 g. per day*. Thus the diet seems to be somewhat deficient in calcium just as it is in ionizable iron (Roy, Pal and Guha, 1939). The consumption of P (1.01 g. per head per day on an average) seems, however, to be almost adequate, as 1 to 1.3 g. of P intake is usually considered sufficient, but, as the figures for the phytin content of the diets show, probably 30 to 40 per cent of the total phosphorus is not available for nutrition. Supplementing the usual diet in the students' hostels with the requisite quantity of milk would apparently satisfy the requirement of extra calcium and phosphorus in an assimilable form.

We wish to acknowledge our gratitude to the Calcutta University Students' Welfare Committee for grants and to the Secretary of the Committee, Dr. A. N. Chatterjee, for much help in carrying out this work.

* Authorities place the maintenance requirement of calcium for health at between 0.45 and 0.55 gm. daily. Allowing for probable retention the accepted value is placed at 0.765 gm. daily, therefore, the calcium deficiency claimed by these authors is not as obvious as they indicate.—EDITOR, *I. M. G.*

EVOLUTION OF GOLD THERAPY IN PHTHISIS

PART II

By S. K. DAS, M.B. (Cal.)

Visiting Physician, Islamia Hospital, Calcutta

THE choice of a case is the keystone to success in gold therapy and the one point that should always be taken into consideration is that gold stimulates the cells of the reticulo-endothelial system lining the capillaries and blood vessels, and therefore if the lesion is not well supplied with them, that is, is a productive lesion, it cannot have much, if any, effect.

An ideal patient is one with sufficient resistance, preferably afebrile or slightly febrile, and with sound kidneys, liver and heart. There should not be too much of a reaction but if reaction occurs at all, he must be able to withstand it. Menstrual periods in females must be respected and in pregnancy that has not been terminated gold must be given with extra care.

Precautions.—An expert opinion as to the suitability of gold therapy must be taken in every case. Proper investigation must be made into the patient's general condition. The patient must not be too toxic and there ought to be fair resistance present.

In cases that show a highly toxic condition the patient must be put to bed, and glucose and alkalies by mouth as well as calcium therapy may be instituted to avert toxic symptoms.

The urine is examined for sugar and albumin, casts, red blood cells, etc. Severe diabetes as well as gross renal defects are contra-indications of gold therapy.

If the liver is suspected not to be functioning well, a liver function test (levulose-tolerance test) may be done and small intramuscular dosage must be resorted to.

In blood diseases, the history will be found useful and in suspected hæmophilia or purpura the bleeding and coagulation time may be determined, and a differential count of leucocytes will be found useful.

Sensitiveness or idiosyncrasy to gold therapy might be determined by a small initial test dosage. There are advocates of the use of sodium or calcium thiosulphate, as well as ascorbic acid but I have never found the need of them in my experience. Glucose is always helpful.

The heart also must be examined, and although it is a fact that a simultaneous affection of the heart suggests grave prognosis yet small doses of intramuscular Myocrisin in oil may be used in such cases.

Liver extract by mouth has been recommended by some as a preventive of reactions.

Careful watch for unfavourable reactions must be always kept and any such reactions must be speedily treated, and gold therapy must be temporarily or permanently suspended.

The lesion

Unilateral cases.—In early caseous types or in semi-productive infiltrations I have seen remarkable results with intravenous gold therapy wherever it was applicable, failing this the intramuscular route is also quite good.

In chronic productive types of infiltration, gold is of doubtful value, but wherever acute exacerbation or recrudescence of the disease has occurred, or the disease tends to increase by caseous process, gold may be applied to check the progress of the disease.

It must be borne in mind that extensive unilateral infiltrations should never be treated with gold alone, but should be combined with surgical measures.

Bilateral cases.—In early bilateral infiltrations gold therapy is the method of choice especially if the lesion be caseous or fibro-caseous in nature. The result should be checked from time to time by x-ray examination and if the progress of the disease process goes unabated the more active side should be surgically dealt with while gold must be continued for the other lung.

If during the course of surgical treatment for one lung with apparent success, the other lung is affected, gold treatment should be at once instituted, if not already adopted.

In moderately extensive bilateral lesions gold may be given a trial along with sanatorium measures, if the pulse and temperature can be controlled by ordinary measures and absolute rest. In a similar case a chance might be taken by surgically dealing with the more active lung, the operation of choice being phrenic evulsion as all other forms are contra-indicated.

The preparations.—The preparations of gold to be used have been fully discussed elsewhere by the writer (Das, 1936 and 1937) I have chiefly used Crisalbine for intravenous and Myocrisin in oil for intramuscular therapy and these preparations I consider the best.

Contra-indications:

1. Absolute

- (a) Gross renal diseases.
- (b) Hepatic diseases.
- (c) Diabetes.
- (d) Grossly damaged decompensated heart.
- (e) Hæmorrhagic diseases.
- (f) Devalitized patient.
- (g) Highly toxic conditions including hyperpyrexia.
- (h) Extensive bilateral lesions.
- (i) Idiosyncrasy.
- (j) After reactionary manifestations.
- (k) Toxæmia of pregnancy.

2. Relative

- (a) Menstrual periods.
- (b) During or after hæmoptysis.
- (c) Hypertension.
- (d) Pregnancy with disorders and abnormalities.
- (e) Highly productive lesions.
- (f) Patients with high temperature and pulse rate.
- (g) Symptoms of intolerance: here some other preparations might be of use.
- (h) Slight degree of hepatic or renal dysfunction.

Mode of administration and dosage

It is important to get as much gold into the system as quickly as is compatible with safety. Women and small weak men should get smaller doses for a longer period.

Crisalbinc.—For a patient with average health, weighing from 7 to 9 stone, a total of about 3 grammes is perhaps the most suitable dose. It has to be given by very slow intravenous injection noting the condition of the patient all the time. It is always desirable that we should have adrenaline chloride solution and a separate small hypodermic syringe ready at hand. A 4.5 to 5 per cent solution is isotonic with blood and 2 c.cm. of a solvent per each 0.10 gm. of Crisalbinc will make an approximately isotonic solution with blood.

The solvent.—Freshly boiled double-distilled water has been recommended by some while others use sterile double-distilled water.

Sodium thiosulphate solution has been recommended with the idea that toxic effects, if any, will be lessened, and as a protection against accidental subcutaneous infiltration. Calcium thiosulphate solution has also been used by some, apparently with the idea of combining calcium with gold. I have seen some using 10 per cent solution of calcium gluconate, evidently with the same idea, and I have watched the cases with interest but failed to find any added advantage in this method.

Crisalbinc is compatible with all the above solvents. I have found 12½ per cent glucose solution (Merck) to be the best. With this I have never seen any toxic by-effects. It saves the kidneys, heart and liver from damage.

The patient

The injection is best given in the morning before the patient gets out of bed. He is made to drink a good quantity of glucose (4 teaspoonfuls to a tumbler) or sugar candy (misri) water about half an hour before the injection. The early morning urine is examined for albumin (a previous sample having been examined for albumin, casts, and red corpuscles) and the urine after the injection is also examined for albumin. The patient is never allowed to have a hearty meal or take exercise one hour before or after an injection.

Though some people recommended an interval of 4 to 5 days for the first few small doses I never like to undertake such a risk and nothing less than a week's interval should be allowed between each injection. The patients must be kept as bed cases at the start of the treatment.

Cardiac tonics have been recommended as a routine process by some authors before each injection.

A chart giving the following information is kept for watching the progress of the disease:—

Temperature, pulse and respiration—morning and evening.

Weight—once a week.

Urine—for albumin before and after each injection.

Blood—for sedimentation rate and wherever possible Schilling count, once a month.

Reactions—if any.

Cough—any improvement or not.

Sputum—total amount in 24 hours and acid-fast bacilli.

X-ray—once in three months in an improving case and oftener if symptoms persist.

General condition—any improvement noticed or not.

Auscultation—any diminution or disappearance of moist râles, noticed or not.

Unless improvement is noticed in a majority of these points the result must be checked by x-ray examination and a suitable treatment adopted.

Technique

The most suitable dose of gold sodium thiosulphate (notably of Crisalbinc) is given below.

The patient is placed in a good light and the assistant is asked to hold the arm with the most prominent vein with one hand above the elbow firmly grasping it with the object of making the vein prominent and the other below the elbow with the object of supporting the forearm.

A platinum needle has been recommended but ordinary needles have been found to be quite good. A 10 c.cm. syringe has to be boiled (and not sterilized with alcohol) for at least fifteen minutes. After properly washing the hands with soap and with alcohol, the syringe is rinsed thoroughly with the needle attached with a 5 c.cm. ampoule of double-distilled water. The desired quantity of 12½ per cent glucose solution is then drawn into the syringe. An ampoule containing the desired dose of Crisalbinc is taken and a portion of the glucose solution from the syringe is expelled into the ampoule; solution is made by gently rotating the ampoule between the palms of the hands and the solution is then drawn back into the same syringe and mixed with the remaining glucose solution in the syringe. It is then injected by the slow intravenous method, the whole process of injection covering at least 15 to 20 minutes. In the meantime the condition of the patient is carefully watched. Change in colour or appearance

of the patient's face is an urgent warning to stop the injection at once and to inject $\frac{1}{2}$ c.cm. of 1 in 1,000 adrenaline chloride hypodermically.

Subject to all the precautions mentioned above specially of urine examination the rest of the glucose solution from a 25 c.cm. ampoule may be given to the patient to drink immediately before the injection.

After this the patient is asked to undergo sanatorium régime for a period of 3 months and the condition is watched all the time, at the end of this period another course of gold may be necessary for which I prefer Myocrisin in oil.

Myocrisin in oil.—Precautions similar to those observed in intravenous medication have to be adopted.

Before the injection the ampoule may be placed in warm water for a short while or shaken violently in order to get a homogeneous solution and the preparation is ready for injection with a thick needle.

Good results.—The patient generally feels a sense of well-being and energy. The appearance becomes brighter and the weight increases. The patient gradually becomes afebrile and later on he is allowed to sit up, walk or take graduated exercise. The pulse and respiration rates come down to normal and the cardiac tolerance test, seen by the counting of pulse and respiration after measured exercise, speedily comes down to normal. The symptoms disappear gradually, and though cough persists longer than any others it also disappears in the long run. The sputum becomes less in quantity and gradually comes down to a negligible amount. The character of the sputum also changes from thick purulent to mucopurulent, then to mucoid and finally to watery. Tubercle bacilli, if present to start with, tend to disappear not because of any direct bactericidal effect, but because the lesion becomes more productive, the supply of nourishment to the bacilli *via* blood and lymph is cut off and they die. Positive sputum towards the end of the treatment with every symptom coming down to normal is not a serious matter, because if we conclude our treatment with sanatorium régime, positive sputum might help to bring about auto-inoculation (Paterson). The evidence of the lesion finally tends to disappear;

the moist râles disappear and finally only a deficient air entry or a slight harsh breathing may be found to be the only remnant of the physical signs.

Laboratory tests.—The Schilling count, if available, is valuable in prognosis. A very convenient method is to observe the erythrocyte sedimentation rate; this can be easily done by the patient's bedside once every month. Provided the external factors such as febrile reactions, catarrh, menstrual periods in females, etc., be carefully avoided, the comparative study of the sedimentation rate will give an indication of the progress of the disease. The reading finally comes down to normal figures (2—5). In an Arneeth count there is a shift to the right.

An increase in the eosinophil cells, lymphocytes and monocytes indicates improvement. According to some French authors large increase in eosinophil and neutrophil cells is a good sign. This is strongly contradicted by Schröder who goes so far as to suggest that it is an indication of gold poisoning and must be avoided.

The vital capacity test may also help but it is not possible in every case.

Radiological evidence of the improvement of the lesion is by far the best test of all and in an x-ray plate we may expect to find that the lesion to some extent disappears, leaving a fibrous tissue scar or the lesion becomes more concentrated and calcified. Some lesions tend to become so proliferative that some retraction of the trachea may be noticed or the mediastinum may be slightly drawn up, due to the traction of the fibrous tissue formed in the lesion.

Unfavourable reactions and their treatment

Toxic shock.—This occurs almost immediately with the injection and sometimes a little later. The patient becomes cyanosed, the body becomes cold and clammy, there is generalized tremor and the patient sometimes loses consciousness. There is profuse perspiration, nausea and vomiting. The pulse becomes feeble and rapid, the respiration hurried, the temperature subnormal and the blood pressure falls.

A careful physician would not allow complete collapse as he will withdraw the needle when there is the slightest indication of shock. The patient is quickly put under the fan and made to lie in bed and $\frac{1}{2}$ c.cm. of 1 in 1,000 adrenaline chloride is quickly injected hypodermically; this may be repeated if necessary. The body is covered with warm blankets and cold water may be sprinkled on the face, and smelling salts administered. Recovery is the rule in a few minutes to half an hour.

Fever.—As we have noted before, we should see that the patient becomes afebrile or mildly febrile before the institution of gold therapy. Febrile reaction may be of two types:—

(a) Sharp rise after the injection which passes off after a day or two. This should not

alarm us and it is no contra-indication to treatment. In some cases it may be advisable not to increase the dose on the next occasion or to make it more dilute and prolong the period of injection, but as a rule these precautions are unnecessary and we may proceed with the treatment.

(b) Low continued temperature for a long period. This is an alarming symptom. We must check our results with auscultation and with x-ray examination and the urine must be examined. It does not indicate, however, that we must stop the treatment but we must see if it is possible to give some surgical aid. If the reaction persists we may use the lower doses of Myocrisin in oil.

(c) Persistent hyperpyrexia is a serious reaction. Gold therapy is absolutely contra-indicated. Alkalies and glucose should be given.

Albuminuria (nephropathia aurea).—Early albuminuria is harmless. There may be a trace of albumin present but no casts or red corpuscles. This is generally due to an overdose and may be described as proteotoxic shock. The dose should be diminished and the treatment suspended for a time. Some people do not even advise a suspension of gold therapy, but it is better not to take a risk. Glucose water and lime or orange juice should be given in plenty and an alkaline mixture can be given. It may be necessary in some cases to give 25 c.cm. of 25 per cent Merck's glucose solution intravenously with insulin 10 units hypodermically daily for a few days when albuminuria should disappear.

Late albuminuria.—A very bold statement has been made by Wingfield: 'My experience, admittedly more limited than many others, is that albuminuria appears in every case and is usually accompanied by the appearance of renal and pus cells in the urine and that it is usually symptomless. If the patient is doing well and the nephritis is symptomless, I think it can be to a large extent disregarded'. We do not agree with this and we take albuminuria with casts and pus cells as a grave symptom. It is highly improbable that toxic nephritis will not cause any symptom and will not aggravate the disease. Nor has it been our experience that albuminuria appears in every case. We are fortunate that not a single case treated by gold under our care showed albumin and casts in the urine.

Gastro-intestinal disturbances.—Vomiting immediately after an intravenous injection is a very common feature. But sometimes nausea may persist for days and there may be actual vomiting. There may be loss of appetite, the digestion may be upset and there may be diarrhoea. Immediate vomiting is not of much importance as it will disappear with a liberal use of glucose and sips of ice. When symptoms of diarrhoea come on calcium will be
